Functional foods are indeed a category that goes beyond providing essential nutrition. They are formulated to offer specific health benefits beyond simply meeting nutritional needs. These benefits can include promoting optimal health, reducing the risk of illness, and enhancing overall well-being. Functional foods often contain bioactive compounds or ingredients that have been demonstrated to have positive effects on health when consumed as part of a regular diet (El-Sohaimy et al., 2023). Microbial-derived functional foods include probiotics, prebiotics, symbiotic, and synbiotic. Functional foods of microbial origin operate by fostering the proliferation of probiotic bacteria, thereby constraining the growth of pathogenic bacteria (Koirala and Anal, 2021).

A probiotic product is expected to maintain a viable cell count of probiotic microorganisms exceeding  $10^6$  colony forming units (CFU) per mL or gram. Numerous factors can impact the viability of probiotics within food products during both processing and storage phases. These factors may stem from intrinsic characteristics of the product, encompassing aspects such as pH, titratable acidity, oxygen levels, water activity, the presence of substances like salt, sugar, hydrogen peroxide, bacteriocins, artificial flavorings, coloring agents, or treatments associated with food processing. Alternatively, these factors can be linked to external conditions, including fermentation parameters, incubation temperatures, heat treatments, cooling and storage conditions, the choice of packaging materials, the scale of production, or specific microbiological traits of the probiotics, such as the microbial strain or the rate and proportion of inoculation (Rodzi and Lee, 2021). Critical considerations in the selection of potential probiotics revolve around their viability during food processing and/or storage, and their survival post-transit through the gastrointestinal tract (GIT), and their capacity to confer health benefits to the host. It is pertinent to note that a majority of bacteria struggle to endure the rigorous conditions encountered during their passage through the upper GIT.

Consequently, the judicious selection of the appropriate probiotic strain assumes pivotal importance in the formulation of products housing viable probiotic cells capable of bestowing health advantages upon consumers (Mojikon et al., 2022). Probiotics offer health advantages to the host when ingested in sufficient quantities. These benefits encompass: *i*) balancing intestinal homeostasis (Probiotics contribute to the equilibrium of the intestinal environment by either eliminating or inhibiting the growth of harmful microbial flora); *ii*) boosting the immune system (Probiotics have the potential to enhance the immune system's functionality, aiding in the body's defence against infections and illnesses); *iii*) reducing the risk of various cancers (There is evidence to suggest that probiotics may help mitigate the risk of certain types of cancer through their influence on the gut microbiota); *iv*) enhancing lactose digestion (Probiotics can improve the digestion of lactose, which can be particularly beneficial for individuals with lactose intolerance) and *v*) other host-microbe benefits (probiotics have been associated with various other advantages, including the prevention of conditions such as cardiovascular diseases, diabetes, and some allergic reactions). Additionally, the consumption of probiotics can lead to alterations in the composition of the intestinal tract's microbiome, further influencing overall health and well-being (Koirala and Anal, 2021). Various microorganisms, including *Lactobacillus rhamnosus* GG, *Lb. reuteri*, *Bifidobacteria*, specific strains of *Lb. casei*, and members of the *Lb. acidophilus* group, have been extensively studied and identified for their probiotic attributes. These microorganisms find prevalent utilization in probiotic food products, notably within the realm of fermented dairy products. Additionally, a subset of other microorganisms, such as *Escherichia coli* strain Nissle 1917, *Enterococcus faecium* SF68, and *Saccharomyces boulardii*, have exhibited therapeutic potential in various applications (El-Sohaimy et al., 2023).

The landscape of probiotic food products has witnessed a notable shift in recent times, transitioning from a predominance of dairy-based offerings to encompass a diverse array of plant-based alternatives, beverages, and snacks (Plessas, 2022). Traditionally, probiotic food products have centered on fermented dairy items, exemplified by kefir and yoghurt. Subsequently, a secondary category of probiotic food products has emerged, embracing fermented fruit and vegetable items, such as pickles or olives, along with select fermented meat products, including sausages. A compelling development in the realm of probiotic food products is the emergence of a new generation characterized by their intriguing non-dairy and non-fermented nature. Within this category, probiotics find incorporation into an assortment of items, spanning breakfast cereals, juices, fruit snacks, chocolates, and confections. Notably, in recent years, non-dairy probiotic foods have garnered substantial attention from the research community, reflecting an evolving consumer demand and an expanding market for such alternatives (Patel, 2017).

## 2. INNOVATIVE PROBIOTIC FOODS

The predominant probiotic products in the market are primarily derived from milk, including yoghurts, cheese, and fermented milk. Nevertheless, the utilization of milk-based probiotic products faces certain limitations, notably due to concerns related to allergies, cholesterol-related conditions, dyslipidemia, and the dietary preferences of vegans. Consequently, there has been a notable upsurge in research endeavours aimed to develop innovative and alternative mediums for delivering probiotics (Plessas, 2022).

### 2.1. FRUIT AND VEGETABLE-BASED PROBIOTIC FOODS

Fruit and vegetable juices have emerged as a promising alternative for probiotic delivery, particularly given the remarkable growth of their global market. Fermented fruits and vegetables are increasingly recognized as healthful food options suitable for individuals of all ages. They stand out as preferred dietary choices due to their exceptional functional and nutritional characteristics, which are enhanced through the fermentation process involving probiotic microorganisms. The health benefits associated with the consumption of fermented fruit and vegetable juices primarily stem from the presence of novel bioactive compounds. These bioactive compounds, such as phenolics and fatty acids, are augmented in quantity and efficacy during fermentation. Additionally, fermented juices contain elevated levels of minerals and vitamins compared to their unfermented counterparts, further contributing to their health-promoting properties (Mojikon et al., 2022). Numerous researchers have explored the suitability of various fruit and vegetable juices as potential raw materials for the production of probiotic juices and related beverages. These juices encompass a wide range of options, including tomato, mango, orange, apple, grape, peach, omegranate, watermelon, carrot, beetroot, and cabbage juices. The probiotics most commonly employed in these formulations consist of different strains from a variety of microbial species, including but not limited to: *Lb. acidophilus*, *Lb. helveticus*, *Lb. casei*, *Lb. paracasei*, *Lb. johnsonii*, *Lb. plantarum*, *Lb. gasseri*, *Lb. reuteri*, *Lb. delbrueckii subsp. bulgaricus*, *Lb.*

*crispatus*, *Lb. fermentum*, *Lb. rhamnosus*, *Bifidobacterium bifidum*, *B. longum*, *B. adolescentis*, *B. infantis*, *B. breve*, *B. lactis*, *B. laterosporus*. Additionally, other microbial species such as *E. coli* Nissle, *Streptococcus thermophilus*, *Weissella* spp., *Propionibacterium* spp., *Pediococcus* spp., *Enterococcus faecium*, *Leuconostoc* spp., and *Saccharomyces cerevisiae* var. *boulardii* have also been considered for their probiotic potential in these juice-based products (Patel, 2017). The criteria used for determining the suitability of a strain in fruit and vegetable juices are; *i*) ability of a substrate to acquire a starter culture; *ii*) the rate and total production of lactic acid, change in pH, loss of nutritionally important substances; *iii*) decrease in nitrate concentration and production of biogenic amines; *iv*) type of metabolism and ability of culture to produce desirable sensory properties of fermented products (Rodzi and Lee, 2021).

## 2.2. CEREAL-BASED PROBIOTIC FOODS

Cereals and their constituent components are poised to attain recognition as functional foods and nutraceuticals. This recognition is attributed to their rich content of antioxidants, vitamins, proteins, energy, and dietary fiber-nutritional elements of paramount importance for preserving human health (Tsafrakidou et al., 2022, Yang et al., 2022). Furthermore, cereals and their various constituents serve as integral substrates for the cultivation and development of probiotic bacteria through fermentation processes (Patil et al., 2022). Rice, wheat, corn, rye, barley, sorghum, millets (Pearl, Kodo, barnyard, foxtail, proso, little millet), pseudo-cereals (buckwheat, quinoa, and amaranth) are the most common cereals consumed by humans (Meena et al., 2023). It has been noted in empirical observations that cereals and their derived products are sometimes lesser or poorer than milk and dairy products. This disparity can be attributed to several factors, notably the cereals' relatively diminished protein content, inadequacy in specific essential amino acids, such as lysine, as well as challenges associated with their digestibility and nutrient bioavailability. These hindrances are compounded by the presence of various anti-nutritional factors, including polyphenols, tannins, and phytate, in conjunction with the coarse-grained nature of cereals. Numerous strategies have been recommended to enhance the nutritional profile of cereals. These encompass genetic enhancements, supplementation with amino acid protein concentrates, or the utilization of other protein-enriched resources like legumes and oilseeds. Furthermore, various processing techniques, such as cooking, sprouting, milling, and fermentation, have been recognized for their potential to enhance the nutritional attributes of cereals. Among these methodologies, fermentation has emerged as a particularly effective approach for augmenting the nutritional quality of cereals (Ganguly et al., 2021). The process of fermenting cereals has been demonstrated to exert positive effects on their bioavailability, digestibility, and organoleptic characteristics. Furthermore, the nutrient composition inherent to cereals has been observed to facilitate the proliferation of probiotic microorganisms. Notably, the presence of prebiotic compounds within cereals can further stimulate the growth and activity of probiotic microorganisms. To date, a variety of probiotics have been used in the development of functional cereal products, including *Lb. plantarum*, *Lb. acidophilus*, *Limosilactobacillus reuteri* and *Lb. casei* (Yang et al., 2022).

## 2.3. MEAT BASED PROBIOTIC FOODS

Meat and its derivative products constitute a fundamental component of human nutrition, notably serving as a rich source of high-quality proteins. Among the various techniques employed for food preservation and storage, fermentation and drying are venerable methods with a historical lineage. In particular, the manufacture of raw cured and ripened meat products, encompassing diverse varieties of sausages and smoke-cured meat items, prominently involves the utilization of fermentation processes. The traditional production of raw cured meat products hinges upon the fermentation of indigenous or supplemented carbohydrates by lactic acid bacteria, present either within the meat matrix or within its surrounding environment (Munekata et al., 2022). This intricate biochemical transformation gives rise to a myriad of compounds, including but not limited to lactic acid, pyruvic acid, alcohols, aldehydes, ketones, and carboxylic acids. The quantitative composition of these compounds profoundly influences the quality attributes and shelf-life stability of the end product. Predominantly, starter cultures comprising lactic acid bacteria (LAB), notably *Lb. sakei*, *Lb. curvatus*, *Lb. plantarum*, and *Lb. lactis*, assume a pivotal role in the fermentation of meat products. LAB hold a preeminent status as starter cultures, exercising paramount influence on the production of fermented meat items. The realm of probiotic meat products represents a relatively nascent and not fully explored domain within the meat industry. Herein, paramount importance is accorded to striking a delicate balance between food safety, sensory attributes, and pro-health properties. The manufacturing of probiotic meat products proves considerably more challenging than conventional counterparts, primarily attributed to the distinctive characteristics of the raw materials. Probiotic bacterial strains suitable for incorporation into fermented meat products must exhibit the

capacity to thrive in the distinctive milieu encountered in fermented goods. Additionally, they must assert dominance over other microbial entities present in the final product. Simultaneously, the sensory profile of the product must remain unaltered. Notably, probiotic bacteria need to be introduced during the preparation of the meat mixture and subsequently during the ripening phase. This strategic inclusion should facilitate the development of robust defensive mechanisms, ensuring the dominance of the probiotic strains over indigenous microflora. In light of these complexities, the production and introduction of probiotic meat products remain at an incipient stage, particularly when juxtaposed with their dairy-based counterparts (Kołożyn-Krajewska and Dolatowski, 2009; Sirini et al., 2022).

#### Abstract

Water stress is an important abiotic stress affecting plant growth, yield, and quality decline. Sudden population growth in the world, global climate change, and many related factors cause an important drought problem in agriculture. To get over this problem, it is necessary to develop strategies for effectively using scarce water resources in plant production. The use of modern cultivation techniques in fruit growing has provided significant increases in the amount and quality of production. Irrigation and fertilization are the most important issues of this production model. Optimizing irrigation and fertilization significantly increases income per unit area while ensuring water consumption and sustainability. If the effect of drought damage on the plant is well-defined, the solution will be much easier. Water stress and drought cause oxidative stress in plants from the accumulation of free radicals. Plants try to resist oxidative stress with some enzymatic and non-enzymatic protection systems. However, the effectiveness of this defense system varies according to factors such as plant type, variety, stress density, and duration. Osmolites accumulate in plants under drought stress; It is divided into 3 parts carbohydrates (such as sucrose, and sorbitol), nitrogen compounds (proline and polyamines), and organic acids (oxalate and malate). Proline is a common osmolyte in plants exposed to water stress. Therefore, subsequent studies focused on elucidating the tolerance mechanisms of drought-resistant plants and on the conservation and transfer of plant genetic resources.

**Keywords:** Apple, Droughty stress, Proline,

#### INTRODUCTION

Stress is physically expressed as the force applied to an object per unit area. Plants encounter many stress factors throughout their lives. Stress is defined as abnormal changes that occur physiologically in plants under the influence of environmental or biological factors. The stress factors that plants encounter throughout their lives are examined under two main titles, and these factors are examined by researchers as abiotic (drought, salinity, radiation, high temperature, frost, etc.) and biotic (pathogen, competition with other organisms, etc.). These stress factors reduce the biosynthetic capacities of plants and change their normal functions, causing permanent damage and even death to the plant (Levitt, 1980; Hale & Orcutt, 1987; Mahajan & Tuteja, 2005; Kalefetoglu & Ekmekci, 2005).

Drought, which is one of the leading natural disasters, causes great losses by causing great damage to the environment and people. Forest fires have become an important problem threatening countries around the world due to global warming, decreasing precipitation, increasing greenhouse gases, insufficient water resources, and climate change (Hekimoglu & Altindeger, 2008). In addition, drought stress has the largest share with 26% among the stress factors observed in cultivated lands worldwide (Kalafatoglu & Ekmekci, 2005). In a general manner, drought is meteorological, it is defined as a period when there is no precipitation, the water content of the soil and plant development decreases significantly, and water scarcity reaches the amount it will suffer (Özcan et al., 2004). Drought is one of the most important environmental stress factors in the world affecting plant growth and yields within the abiotic stress group (Glombitza et al., 2004) and climate changes in recent years indicate that this situation is becoming more serious (Wang et al., 2003). Globally, drought stress, combined with high temperatures and radiation, significantly limits plant life and crop (Chaves et al., 2003; Kapluhan, 2013). Drought stress is common in areas where precipitation is not sufficient, as plants cannot find the moisture they need to sustain their lives (Sircelj et al., 2007).

Plants respond to the situation with morphological, biochemical, and metabolic changes that they show during the drought stress process. In plants exposed to drought stress, cell division, and differentiation come to a

standstill, which negatively affects plant growth and development. The intake of mineral substances decreases in the plant and the yield is directly affected by slowing down the plant development with the decrease of turgor pressure in the plant under the influence of drought and the decrease of the amount of water lost by sweating. Stress has been determined to reduce trunk diameter and leaf area, as well as plant height and fresh root weight in pear trees exposed to drought. As a result, it has been found that plants exposed to water scarcity are more vulnerable to other biotic and abiotic stresses (Romo et al., 2001; Capell et al., 2004; Caruso et al., 2008; Farooq et al., 2009; Gür, 2018; Küçükymuk, 2020; Faizi & Öztürk, 2022).

Even though drought in nature is caused by a combination of environmental factors, plants stimulate many physiological, biochemical, and molecular responses to water scarcity and, accordingly, they can develop tolerance mechanisms that adapt to limited environmental conditions (Arora et al., 2002). Stress tolerance is the ability of plants to survive against adverse environmental conditions. Plants form a two-way survival mechanism against drought stress, either by avoiding stress or by developing stress tolerance (Mundree et al., 2002). Plants draw water from the soil more strongly with the decrease in the amount of water lost by transpiration in drought stress and morphological changes in leaves and roots (Çırak & Esendal, 2006; Kutlu, 2010). When plants are under drought stress, they try to reduce water loss and transpiration by shedding their leaves and reducing leaf areas. As the leaf area decreases, the amount of CO<sub>2</sub> per unit area also decreases. This decrease negatively affects the photosynthesis of the plant. While the plant increases the wax layer on the leaf surface to reduce water losses, the cuticle layer reflects the sun's rays, reducing the effect of heat and therefore reducing the rate of transpiration (Göksoy & Turan, 1991; Türkan et al., 2005). The relative moisture content is positively related to the photosynthesis rate. Leaf water content, relative moisture content, and transpiration rate decrease significantly in plants exposed to drought stress (Anjum et al., 2011). When the water decreases, the plant tries to preserve the available water by closing its stomata so as not to lose more water (Turkan et al., 2005). In addition, respiration, translocation, ion intake, carbohydrate, nutrient assimilation, and growth promoters are also damaged in combination with drought conditions (Siddiqui et al., 2015).

Dehydration causes a decrease in cell volume, an increase in cell cytoplasm concentration, and a constantly increasing dehydration of protoplasm, which in this case leads to an increase in reactive oxygen species (ROS). The activity of peroxidase or glutathione reductase decreases oxidative stress caused by drought. Adjustment in plants occurs through the deposit of low molecular weight organic solutions in water stress, osmotic. These osmolytes are found in plants as soluble carbohydrates and proline. One of the first reactions of the plant to reduce water stress damage is known as Proline deposition (Anjum et al., 2011; Marcińska et al., 2013; Adak et al., 2018). Drought resistance is behavior specific to species and even varieties, and it is of great importance to determine the method and ability of the plant to avoid stress in order to determine the tolerance of plants under stress conditions (Özcan et al., 2004). Various species-specific enzymatic defense systems have been developed against stress-induced oxidative stress in plant cells in addition to the tolerance mechanisms created against the mechanical damage caused by drought (Bian & Jiang, 2009). A high amount of antioxidant enzyme activity in plants significantly reduces the oxidative damage caused by the cell size in tolerance to drought stress. But the effectiveness and success of these antioxidant enzymes produced during drought vary depending on the type, variety, severity of stress, and duration of the stress of the plant (Sharma & Dubey, 2005; Türkan et al., 2005; Bian & Jiang, 2009).

## WHAT IS STRESS

In our era, the word stress is included in our life in this way. The word stress is used in engineering fields such as physics and mechanics to fields related to human and animal health such as medicine and veterinary medicine. A kind of defense or even a psychological reaction occurs in the organism against the pressure or tension they encounter in creatures exposed to stress. Thus, ecological stress is defined as any factor that forces plant metabolism and the internal balance of the plant in its natural environment to change, as well as causing deficiencies in plant development and growth (Shulaeva et al., 2008; Nader et al., 2019). Physiological and biochemical events such as hormonal balance, respiration, photosynthesis, and nutrient transport are affected in plants exposed to stress, causing plant metabolism to slow down or stop. Plant development is negatively affected, resulting in a decrease in yield and quality as a result of all these reactions. Stress factors are studied under two groups, Biotic factors are stress factors caused by infection of microorganisms (fungi, bacteria, and viruses) and attacks of harmful animals. Abiotic stress conditions involve many stresses caused by complex environmental conditions such as strong light, ultraviolet, high and low temperatures, frost, drought, salinity, heavy metals, and insufficient oxygen (Lichtenhaler et al., 1996; Hirayama & Shinoza, 2010). Naturally,

biological tensions that occur as a result of stress in a living individual are also expected to be observed. What is expressed here as biological stress is the change in plant metabolism and morphology and the decrease in growth. According to this, if the plant is able to react to the environmental factors it lives in at the maximum level, it means that it has not started to be affected by environmental factors at the stress level. Contrary, if changes in factors other than optimal values cause changes in the response level of the plant as a result of tension, this condition is considered stress. Plants can naturally adapt to stressful conditions. Despite being exposed to stress conditions, these specialized plants are able to survive in the environment they are in and complete their life cycle (Boscaiu et al., 2008; Büyük et al., 2012; Noctor et al., 2018; Wang et al., 2019).

## **DROUGHT STRESS**

Drought stress is one of the most important and common abiotic stress factors for plants in many parts of the world, especially in drought and semi-drought regions. Drought is used as a general term to describe atmospheric or weather events and is usually used to describe a period that will pass without precipitation (Jaleel et al., 2009; Dai, 2012).

Drought is divided into four main titles: meteorological, agricultural, hydrological, and socio-economic. Drought begins as a meteorological drought, develops as an agricultural and hydrological drought, and its effects become visible as a socio-economic drought. While meteorological drought is based on precipitation and is defined as a decrease in precipitation below normal values for a long time, the increase in air temperatures and atmospheric CO<sub>2</sub> together with global climate change affects the precipitation regime negatively in many regions and causes drought (Arbona et al., 2013). Agricultural drought is defined as the amount of water that plant roots can use in the soil that falls below a certain level or the inability of moisture in the soil to be taken up by the plant. In other words, it is seen that the amount of water lost by transpiration from the leaf surface is more than the amount of water taken up by the plant roots (Keyvan, 2010; Mengü et al., 2011; Dai, 2012; Örs & Ekinci, 2015). Imbalances in water consumption and water loss of the plant usually reveal themselves in cases where the water potential of the soil is lower than the water potential of the plant roots. Continuous water loss through transpiration and evaporation is positively or negatively affected by changing atmospheric conditions (Shao et al., 2008; Mafakheri et al., 2010; Dai, 2012; Trenberth et al., 2014). As a result, agricultural drought occurs immediately after meteorological drought depending on climatic conditions (Jaleel et al., 2009; Barriopedro et al., 2012; Dai, 2012). Hydrological drought, the development of large water losses in rivers, lakes, and underground water resources, the decrease in precipitation as a result of global warming and climate change, due to insufficient water reserves, the rapid increase in the world population and with this increase, the amount of water consumed per capita exceeds the standards, puts countries at risk of drought and desertification. Socioeconomic drought, on the other hand, occurs as a result of imbalances caused by other types of drought and is observed as a result of the deterioration of the economic balances of countries (Mishra & Singh, 2010). Climate change is a major factor inducing drought stress worldwide and disruption of the natural balance is a result of these changes, drought resulting from climate change is limiting crop yields by preventing many crops from being grown locally. Water losses in the plant and soil increase together with a combination of factors, and then it becomes easier for the plant to be exposed to water stress (Mafakheri et al., 2010; Dai 2012). As we have witnessed in many parts of the world, it is seen that precipitation decreases and is irregular in our country, especially in summer months due to climate change and global warming (Kaynaş & Kaynaş, 2003). As one of the effects of climate change, it is predicted that it will cause climate changes in our country, temperature values will increase with this change, and this rising temperature can seriously affect semi-drought and drought regions that do not have enough water. Irregularity in the amount of precipitation and its distribution over the months is an inevitable result that will negatively affect plant yield and agricultural production (Ozturk, 2002). Turkey will be among the countries in the risk group regarding climate change. It is predicted that if measures are not taken, the consequences will be greater and our Central Anatolia and Mediterranean regions will be more affected by global warming in the future (Sircelj et al., 2007). Changes in production techniques have become necessary to ensure sustainability in agriculture. These changes in production techniques necessitate some practices that reduce water stress in order not to face the bigger problems of the future. Adjusting the planting time, mulch application, some microorganism applications, and fertilizer applications to reduce moisture losses in the growing environment and plant can be given as examples of changes (Jaleel et al., 2009; Jing-min et al., 2010; Desoky et al., 2018). According to the United Nations World Agricultural Organization (FAO), drought damage is defined as the percentage of years in which crops are damaged due to reduced humidity (Hawkish & Cuning, 2014).

## THE EFFECT OF DROUGHT STRESS ON THE PLANT

Water is one of the abiotic factors and is an important limiter affecting plant growth, development, and yield. Although drought stress is a multidimensional stress, the response of plants to water stress varies depending on the type of plant, the age of the plant, the growth and development period, the level and continuity of drought, and physical factors. Plants show resistance to the negative effects of stress with the changes they make in their physiological, morphological, ecological, biochemical, and molecular properties in order not to succumb to different stress factors (Kayabasi, 2011; Bhargava & Sawant, 2013; Marcińska et al., 2013). The stress factor also negatively affects plant growth, yield quantity, and quality. The decrease in plant growth due to stress develops due to the fact that shoot and root meristem tissues are affected and the cells in these tissues stop division and expansion. The cease of cell division or expansion is directly related to a decrease in the rate of photosynthesis due to a lack of water (Jaleel et al., 2009; Anjum et al., 2011; Zlatev & Lidon, 2012; Nezhadahmadi et al., 2013).

The symptoms of drought stress vary depending on the plant type, growth stage, growing conditions, and other environmental factors (Arbona et al., 2013; Bhargava & Sawant, 2013; Nezhadahmadi et al., 2013). The severity of the drought, the duration of the drought, soil physicochemical conditions, and plant resistance are other effective factors that trigger the severity and effect of drought stress symptoms in plants. In general, the symptoms of drought stress are observed in the plant in the form of loss of leaf turgor pressure, sagging, fading, etiolation, yellowing, and finally early leaf fall, respectively (Bernacchia & Furini, 2004; Farooq et al., 2009; Jaleel et al., 2009; Zare et al., 2011; Bhargava & Sawant, 2013; Sapeta et al., 2013; Akhtar & Nazir, 2013). The effect of drought stress on plants can be summed up in two main titles fading and drying. The disappearance of leaf turgor, sagging, fading, etiolation, yellowing, and early leaf fall can be defined as the beginning and end stages of these two main headings (Smirnoff, 1993; Bhargava & Sawant, 2013; Sapeta et al., 2013; Akhtar & Nazir, 2013). If plants are exposed to drought conditions for a long time, the leaves wilt, especially in deciduous plants in winter, and the prolongation of the duration of arid conditions, this causes significant leaf losses in the plant, and these losses can lead to the weakening or even death of the plant. Plants exposed to a slight lack of water, which reaches about 70% of the water pressure in the leaves, carbon dioxide intake, and photosynthesis process are restricted due to the closure of the stomata, and the plant weakens and signs of pallor begin to appear. The first visible and known symptom of drought stress is wilting (Zeppel et al., 2015). Drying can be defined as excessive water loss, which can lead to complete disruption of metabolism and cell structure and stop enzyme-catalyzed reactions (Smirnoff, 1993; Kalefetoglu & Ekmekci, 2005). The plant loses turgor pressure in wilting, and the leaf water content decreases, and this decrease causes the collapse of cells. When the amount of water required for the plant is provided, it regulates the turgor pressure and reduces the severity of wilt, allowing the plant to return to its former state. However, since the wilting has reached a very advanced stage in the drying event, it is not possible for the plant to return to its former state (Akinci & Lösel, 2012; Kaçar, 2015). Most of the vegetative tissues of vascular plants that are sensitive to drying out are unable to enter the healing process after the proportional water content falls below 30% (Kalefetoglu & Ekmekci, 2005). When the plant cannot supply the water it needs from the root zone and this creates stress, the plant tries to get rid of this problem by reducing water losses or reducing its internal water potential below the soil water potential in order to maintain water intake (Bray, 1997; Rahdari & Hoseini, 2012), and the first effect that will occur as a result of the continuation of the problem is the loss of turgor pressure (Barlow et al., 1980).

Plant growth and development are significantly affected in drought conditions. The extent of damage and damage caused to the plant by these conditions depends on the duration of water scarcity. The fact that the water lost by transpiration from the leaves cannot be met by the plant roots and the turgor loss as a result of this water loss shakes the plant metabolism. Plasmolysis occurs in the leaf cells as a result of drought, which causes the leaves to wilt (Günay, 2005). The plant increases root development by slowing down trunk elongation and growth during the first periods of drought in order to defend itself and reach more water (Ozturk, 2015). On the other hand, if the drought lasts longer than the plant's endurance, the trunk and root development at this stage stops completely due to stress, the leaf area and the number of leaves decrease, even some leaves turn yellow and fall out. A decrease in the rate of photosynthesis and decreases in chlorophyll content in dry conditions are considered typical signs of oxidative stress, which leads to pigment photooxidation and chlorophyll degradation (Anjum et al., 2011; Marcińska et al., 2013). The effects of drought on the plant not only affect plant water relations by reducing water content, turgor, and total water, but also affect the closure of stomata in plants under stress, reducing gas exchange and transpiration, and bringing the carbon assimilation (photosynthesis) rate to a standstill (Lisar et al., 2012). The decrease in plant growth and growth occurs due to the cessation of cell division in the shoot and root meristems and the

expansion of cells. The cease of cell division or expansion is directly related to the decreased rate of photosynthesis due to water stress (Anjum et al., 2011). Photosynthesis is the most important process for plants. Growth and health are also affected due to any disruption in the photosynthesis process, and plant productivity (Zargar et al., 2017). Leaf water content, relative moisture content, and transpiration rate decrease significantly in plants exposed to drought stress. There is a positive relationship between the relative moisture content and the rate of photosynthesis (Anjum et al., 2011). Apart from that respiration, translocation, ion uptake, carbohydrate, nutrient assimilation, and growth promoters are damaged together with drought conditions (Siddiqui et al., 2015). One of the negative aspects of drought stress is that it leads to an increase in reactive oxygen species (ROS). The activity of peroxidase or glutathione reductase decreases oxidative stress caused by drought. Osmotic adjustment for water stress in plants takes place by deposition of low molecular weight organic solutions (Marcinińska et al., 2013). These osmolytes exert their effects as soluble carbohydrates and proline in plants. The deposition of proline in the cytosol is known as one of the first plant responses to reduce damage under water stress conditions (Anjum et al., 2011).

### **PLANT REACTIONS TO DROUGHT STRESS**

Plants are able to flex their growth and development mechanisms in such a way that they are minimally damaged by changes that may occur in environmental conditions, and even adapt to be minimally affected by environmental changes when exposed to certain climatic conditions for a long time. The distribution of plants belonging to the same species in regions of the world with different climatic characteristics is the best indicator of their ability to adapt to very different environmental conditions (Dolfeus, 2014). Drought stress, which has an important effect on plant growth and development, reveals many morphological, physiological, biochemical, and molecular responses, and thus the plant activates different tolerance mechanisms in order to adapt to adverse environmental conditions or survive (Pou et al., 2013; Nader, 2019). As an example of the tolerance effort of the plant, changes in the form of an increase or decrease in aquaporin gene expression are observed in plants under drought stress (Tyerman et al., 2002). The tolerance responses of the plant and the size of drought symptoms in the plant may vary depending on the type of plant, the stage of development, growing conditions, and other environmental factors (Arbona et al., 2013; Bhargava & Sawant, 2013; Nezhadahmadi et al., 2013). In other words, the factors that induce drought symptoms in plants have been determined as drought severity, drought duration, soil physicochemical conditions, and plant strength. and affected by drought stress, the effects, and symptoms of stress in general include loss of leaf turgor, drooping, wilting, etiolation, yellowing, and premature leaf fall (Bernacchia & Furini, 2004; Farooq et al., 2009; Jaleel et al., 2009; Zare et al., 2011; Bhargava & Sawant, 2013; Sapeta et al., 2013; Akhtar & Nazir, 2013). They developed three different strategies for surviving or recovering from the above-mentioned drought stress effects in plant physiology: adaptation, drought avoidance, and drought tolerance. Drought adaptation refers to the capacity to withstand drought processes, while avoidance is a method of strategies that will prevent the reduction of water potential in protoplasm from lasting long enough to be harmful, and tolerance is defined as showing more desiccation without harming the protoplasm (Gurel & Avcioglu, 2001; Mundree et al., 2002).

Leaf water content and turgor loss occur in the plant and the plant closes its stomata for defense and to prevent further water loss with drought stress or a decrease in soil water content in drought conditions (Jaleel et al., 2009; Akinci & Lösel, 2012; Küçükyumuk, 2020). One of the simplest responses of the plant under drought stress conditions is the closure of stomata and the reduction of CO<sub>2</sub> exchange. Photosynthesis is prevented depending on the severity of the stress and if this situation continues for a long time due to the behavior of the plant, it can lead to plant death (Jaleel et al., 2009). A plant needs water to control its internal temperature. Most of the water is lost through stomatal transpiration, more than the amount stored in plant cells. This loss of water allows the leaves and the plant to cool down. Plants cannot maintain their body temperature when faced with factors such as water scarcity and drought (Adams et al., 2009). The relative growth rate of the plant decreases and the plant height also decreases under water stress conditions (Lipiec et al., 2013). Lack of water reduces plant growth, leaf surface area, and dry matter; it also causes cell membrane degradation, pigment damage, chlorophyll content decrease, and root growth slows down and stops. Plant tissues are also damaged during drought stress and deaths occur during long-term drought (Farooq et al., 2009). It is observed that while total phenolic substance, soluble sugar, proline, antioxidant, enzyme activities, Fe, Mg, and Mn values increase in the shade of damage to tissues and plant cells in plants under drought stress, N, Cu, B, Zn, P, Ca, and K values decrease (Gür, 2018). A high amount of sugar deposition occurs in plant tissues damaged by drought stress, which significantly hinders photosynthesis and causes stunted growth and necrotic leaves to form in the plant (Sami et al., 2016).

Drought conditions also change the plant cell turgor pressure, i.e. the amount of water potential. It is very important to maintain the osmotic balance in order for plant cells to be minimally affected by water stress. For this purpose, when plants perceive drought stress, they synthesize a group of soluble substances called "osmolytes", which play a role in maintaining cell turgor balance and accumulate in their cells. Examples of osmolyte substances can be given from different groups such as free amino acids such as asparagine, proline and glycine, betaine, organic acids, and carbohydrates. Osmolytes that accumulate in plant cells and play a role in maintaining water balance do not directly affect or increase the plant's resistance to drought stress. However, as they balance the intra-leaf water pressure, they increase the conductivity of the stomata, ensure the continuity of photosynthesis, and thus help growth. Osmotic regulation is one of the important components in adapting to drought stress. The leaf water potential helps to protect the cellular turgor and thus delays fading. The preservation of water balance and the ability to maintain cell metabolic activities through osmolytes, albeit limited, provide short-term resistance to plants in arid conditions. If drought and stress conditions persist for a long time, osmolyte deposition will not be enough to compensate for the loss of turgor caused by lack of water and will not prevent the plant from being affected by stress. The main intracellular function of proline is to protect membrane systems by preventing lipid oxidation and protecting protein structures through the compounds they form. It reveals that proline may also be involved in signal transduction and may be an important free amino acid that plays a role in regulating mitochondrial functions, cell division or death, and even gene expression levels (Anjum et al., 2011; Liang et al., 2018; Kishor & Sreenibasulu, 2014). As drought stress factors increase in drought-resistant plants, proline synthesis by the plant increases, providing resistance to structural denaturation caused by drought stress, and plant cell structures are protected by proline, which is responsible for protein synthesis (Xoconostle-Cazares et al., 2010). Osmolytes, which are protective molecules, are proteins that function in the cleaning of ROS caused by stress. They function as osmotic regulators and osmoprotectants. They retain water in the cytoplasm and protect the health of cellular structures by facilitating the retention of sodium in apoplasts and vacuoles (Beshir et al., 2016). If the stress conditions persist for a long time, the deposition of osmolytes will not be enough to compensate for the loss of turgor caused by lack of water (Ozturk, 2015). Some reactive oxygen species are formed in hydroxy (OH), superoxide ( $O_2^-$ ), hydrogen peroxide ( $H_2O_2$ ), and singlet oxygen ( $^1O_2$ ) in drought conditions. Reactive oxygen compounds that deposit under stress conditions are actually a natural by-product of cell metabolism and are components that play an important role in the signal transduction mechanism (Anjum et al., 2011; Cabello et al., 2014). In case of excessive deposition of these components, they can lead to cell death by inducing lipid peroxidation, protein reduction, and DNA fragmentation. In addition to the negative effects of the components, reducing and preventing the deposition of these reactive oxygen compounds formed during drought stress is an important factor in the plants' struggle with stress conditions and even their survival. Plants struggling with oxidative stress caused by the deposition of reactive oxygen compounds use enzymatic (superoxide dismutase, peroxidase, catalase, ascorbate peroxidase) or non-enzymatic (glutathione, ascorbate, tocopherols, carotenoids) antioxidant molecules. While the main task of non-enzymatic antioxidant molecules is explained as the protection of photosynthetic membranes, enzymatic antioxidant molecules prevent their deposition by reducing reactive oxygen compounds (Farooq et al., 2009; Anjum et al., 2011; Dolferus, 2014; Osakabe et al., 2014). It can be determined whether oxidative signal or damage will occur in the plant thanks to the balance established between the amount of reactive oxygen ROS produced by the plant exposed to stress and the antioxidant enzyme activity to counteract it (Moller et al., 2007). The capture of reactive oxygen ROS by plant enzymes and their ability to reduce their harmful effects may be related to the drought tolerance of plants (Tsugane et al., 1999).

It has been determined that the artificial application of various plant growth regulators and osmotic preservatives such as cytokinin, abscisic acid, proline, glycine betaine, polyamine, and salicylic acid to plants has significant potential in increasing the plant's drought tolerance (Travaglia et al., 2007). It has been reported that ABA, known as the stress hormone in leaves, is synthesized in the roots during dry periods, causing stomata to close and changes in the expression of genes (Stellfeldt et al., 2018).

## RESULT

In general, plants encounter many negative factors such as salinity, drought, pollution, heat, and cold throughout their lives, and growth and development events under normal conditions are damaged by these conditions. These factors that cause negative effects on the development and behavior of plants and the plant's different reactions to these conditions are generally defined as stress. When plants are exposed to these stress conditions, the faster they react to adverse conditions within their own bodies, the greater their chances of getting rid of adverse conditions. Of course, the reaction to stress conditions will be possible in drought-resistant or tolerant plants. Plants that are not drought tolerant should be excluded from this issue. It will be

possible to develop plants with a high tolerance level that can provide better adaptation to environmental conditions in order not to disrupt production. It will be possible to produce these species in drought regions by transferring resistance genes to such plants by conducting breeding studies with hybridization or other gene transfer methods in plants that do not have tolerance and resistance to stress conditions. In addition, soil and water erosion will be prevented by using protective tillage methods instead of traditional tillage in semi-drought and drought regions, and it will be possible to reduce production costs by keeping soil moisture for a longer time. In our world where we feel the effects of global warming stronger day by day, and in our world where food shortages may occur due to the increase in population density, decrease in arable land, and destruction of water resources in the future, it has become very important to reduce product losses caused by stress. It is our duty to take action on a global scale and put a stop to this global climate change before it is too late.

#### Abstract

In this study, two pea genotypes with different seed coat colors (green and brown) grown locally in Turkey were investigated based on biochemical components. The samples extracted from the grains of these two genotypes were evaluated. Total water-soluble protein, total flavonoids, total phenolics, H<sub>2</sub>O<sub>2</sub> scavenging capacity, carotenoids, FRAP antioxidant capacity, CUPRAC antioxidant capacity, and total dry matter parameters were measured. For all the parameters examined, the difference between pea seeds with brown and green seed coat colors was statistically significant. In general, the studied characteristics of green peas were higher than brown peas. only for H<sub>2</sub>O<sub>2</sub> scavenging capacity and dry matter content brown peas had higher results.

**Key words:** Brown pea, carotenoid, flavonoid, Pisum

#### INTRODUCTION

Edible grain legumes have many superiorities in terms of nutritional value compared to other plant-based foods. Their seeds contain 20-25% protein. There are some components in legume seeds that have positive or negative effects on their nutritional value. While anti-nutritional elements including enzyme inhibitors, lectins, gassing agents, polyphenols, tannins, phytic acid, and saponins can sometimes have detrimental impacts on nutrition and health, high protein, low fat content, vitamins, minerals, and dietary fibers often have good benefits (Pekşen and Artık, 2005).

Approximately 2/3 of the world's population lives on a grain-based diet that lacks sufficient protein. (Ekingen, 1992). Among the vegetable protein sources, the most The most protein is produced from edible grain legumes (Şehirali, 1988). Possessing due to its amino acid composition and acceptable functional properties peas are an alternative vegetable that can be used to enrich food products. protein source (Tömösközi, et al., 2001).

In 2021, the world dry pea cultivation area, which is the subject of field crops discipline, was 7.043.605 ha and the production amount was 12.403.521 tons (Anonymous, 2023). The annual production amount of green peas, which is the subject of the horticulture discipline, is 20.529.759 tons. This production was carried out on an area of 259.0367 ha. In 2020, the dry pea cultivation area in Turkey was only 679 ha and the production amount was 1805 tons. However, the production amount of green peas is 111625 tons on an area of 11.647 ha. Turkey ranks almost last in world dry pea production (87th among 95 countries). In fresh pea production, Turkey ranks 45th among 82 countries.

Turkey has a very important position in the world in terms of plant gene resources due to its geographical structure and different ecological conditions. Genetic material that fully adapts to the ecological conditions of the regions where they grow is the assurance of the future of agriculture and thus of humanity (Özgen, et al., 2000).

Antioxidants have long piqued the curiosity of the scientific community and the general public due to their ability to defend against free radicals (Bhoyar et al., 2018). Although there is information on the nutritional makeup of green peas, there is still a huge knowledge vacuum when it comes to the varietal assessment of antioxidant chemicals. There is a lack of research as well, much of which concentrates on methods for extracting antioxidants (Xu and Chang, 2008; Oomah et al., 2011) and the antioxidant capabilities of green-pea seeds or seed coatings (Amarowicz et al., 2004; Petchiammal and Hopper, 2014).

The main hypothesis of this study was that there is a difference between some biochemical contents of pea grains with brownish seed coat color and pea grains with conventional green color.

## MATERIALS AND METHODS

The experiment's agroclimatic site was in Turkey's Kayseri district in Middle Anatolia. The pH of the soil in the experimental plot was 7.1, making it neutral. Two different genotypes of brown and green peas were the plant material. Plants were grown in Erciyes University Cool Climate Vegetables Production and Research Area (ERUcsvra). Analyses were performed in the physiology laboratory of the same university. The procedure described by Danilcenko et al. (2017) was used to prepare data for analysis on pea seeds. The materials were completely dried at 60 degrees Celsius for 24 hours before being ground up in a plant grinder. Each clone's and organ's 3 g of powdered materials was homogenized for 2 minutes with 25 cc of pure methanol before being kept at +4°C for 16 hours. The supernatant was taken out and centrifuged for 20 minutes at 10,000 rpm for analysis (Thaipong et al. 2006). Both the copper (II) ion reducing antioxidant capacity determination (CUPRAC) method and the ferric reducing antioxidant power methodology (FRAP) (Zhang et al., 2013) were used to assess antioxidant capacity. The total quantity of phenolic compounds was determined using Singleton and Rossi's (1989) Folin-Ciocalteu method. Using the method outlined by Zhishen et al., the total quantity of flavonoids was determined. The technique suggested by Ruch et al. was used to calculate the hydrogen peroxide removing capacity (H<sub>2</sub>O<sub>2</sub>). The amount of soluble protein was determined using a method that Lowry et al. (1951) published.

To assess the significance of the data's variance, an ANOVA test was utilized. The least significant difference (LSD) test was used to compare results between groups when significant differences were discovered.

## RESULTS and DISCUSSION

The differences between the results obtained for all measured parameters were statistically significant. In all parameters except H<sub>2</sub>O<sub>2</sub> scavenging capacity and total dry matter percentage, pea seeds with green shell color had higher results. According to the results, green pea seeds had the highest total carotenoid concentration (0.785 g/g DW), followed by brown pea seeds (0.679 g/g DW) (Table 1).

**Table 1.** Some biochemical characteristics of brown and green peas

Seed Color	Chlorophyll a (mg/g)	Chlorophyll b (mg/g)	Carotenoid (mg/g)	Soluble Protein (mg/ml)	Dry weight (%)
Brown	1,921 b	0,998 b	0,679 b	12,103 b	25,957 a
Green	7,187 a*	4,880 a	0,785 a	21,563 a	15,802 b
LSD	0,239	0,160	0,033	0,793	0,975

\*Significant ( $p < 0.01$ ), Means within a group that have a different small letter are significantly different from each other

In terms of H<sub>2</sub>O<sub>2</sub> scavenging capacity, brown pea seeds had higher values than green seeds (32.609% and 8.633%, respectively) (Table 2). Regarding total phenolic matter concentration, green pea seeds ranked in the lead (11.529 GAE mg/g). Brown peas were found to have the lowest phenolic content (5.603 GAE mg/g). The ranking of the analyzed peas according to total flavonoid content was the same as for total phenolic matter. The total flavonoid content of green shelled seeds was 1.86 times higher than that of brown shelled seeds (84.238 and 45.190, respectively).

**Table 2.** Antioxidant capacities and some other biochemical properties peas

Seed Color	H <sub>2</sub> O <sub>2</sub> Removal capacity (%)	Total Phenolic Content (GAE mg/g)	Total Flavonoid Content (mg Quercetin/g)	FRAP (mM Tloroks/g)	CUPRAC (mM Troloks /g)
Brown	32,609 a	5,603 b	45,190 b	7,698 b	5,074 b
Green	8,633 b	11,529 a	84,238 a	10,804 a	5,417 a
<i>LSD</i>	<i>1,081</i>	<i>0,411</i>	<i>3,065</i>	<i>0,426</i>	<i>0,238</i>

\*Significant ( $p < 0.01$ ), Means within a group that have a different small letter are significantly different from each other

Various methods may be used to assess the antioxidant activity of plant extracts, but no single standard has been created because of how complex the extracts are. In the current study, the antioxidant activity of pea varieties with two distinct seed coatings was assessed using the CUPRAC radical scavenging test and the FRAP assay. The highest value was found using FRAP research in green pea seeds (10.804). Brown-shelled pea values (7.698) came after that. The CUPRAC results showed the same arrangement. Green-shelled pea seeds showed the highest scores in our investigation (5.417 and 5.074, respectively).

Evaluation and selection of variations with one or more desired traits are necessary for breeding and processing methods. The results of this study showed that two pea cultivars cultivated under same conditions but with varied seed coat colors showed substantial variance in their biochemical characteristics.

According to several studies (Leonardo and Doré, 2011; Vajdy, 2011), flavonoids have several significant biological actions, including impacts on photoaging, allergies, inflammation, and cardio protection. Additionally, according to Amarowicz et al. (2007) and Troszyska and Ciska (2002), flavonoids are the primary source of antioxidant activity in plants. In order to replace the usage of artificial antioxidants in meals, peas might be employed as a natural source of antioxidants. The total phenolic, total flavonoid, CUPRAC, and FRAP antioxidant capacities of green pea were substantially greater than those of the brown pea type, according to the results. Black soybeans, on the other hand, have a significantly higher phenolic content and antioxidant activity than light-colored beans, according to Xu and Chang (2007). Furthermore, Shem-Tov et al. (2012) discovered that FRAP, total flavonoid, and total phenolic content were greater in chickpea seeds with dark, yellow, and high color intensity compared to seeds with lighter colors. Red and black sword beans have higher phenolic contents and antioxidant capabilities than white sword beans (Gan et al., 2016). Except for hydrogen peroxide scavenging capabilities, these results go against everything we found. The total phenolic content of the green and brown pea genotypes evaluated in the current experiment ranged from 5,603 to 11,529 mg GAE/g and from 45,190 to 84,238 mg CE/g, respectively, with little variation between them. These findings have higher confidence than those of Klepacka et al. (2011), who found that the phenolic matter concentration of pea cultivars ranged from 28 to 42 mg/100 g. They agreed with the stated relatively little amount of variance, though.

## CONCLUSION

The importance of pea, a substantial source of protein and minerals in the vegan diet, is increasing due to the various benefits associated with hunger control and intake. The study clearly demonstrated significant genetic diversity in the two pea genotypes examined for biochemical contents and their relationship to seed-coat color. The green pea variety had the highest total flavonoid content, total phenolic content, antioxidant activity and carotenoid values, brown pea seeds may have potential health benefits for capacity with more H<sub>2</sub>O<sub>2</sub> scavenging capacity than light-colored seeds.

## ACKNOWLEDGEMENTS

#### Abstract

Apple, one of the temperate fruit types, is grown in Turkey in large quantities, especially in the Karaman region. Although Turkey is at the top of the world in apple production, it, unfortunately, lags behind many European countries in exports. One of the reasons for the low exports is mainly the low quality of production. The fact that the thinning of fruit trees in our country is not carried out correctly and to an appropriate extent is one of the main reasons for the low level of exports. Regardless of proper cultural measures such as pruning, fertilization, and irrigation at the right time and in the right way, thinning is a method that directly affects fruit quality. Thinning is done manually, mechanically, and chemically in three different ways. Because mechanical thinning damages the fruit, it is rarely used in commercial production. This method is preferred in organic farming, where the use of chemicals is limited. In our country, thinning is usually done manually, and chemical thinning is used as an alternative to save labor and production costs. Plant growth regulators such as NAA, 6-benzyl adenine, carbaryl, etephon, and NAD are used as chemical thinning agents. In this study, the factors affecting the thinning effect and success and the methods used by the producers were investigated.

**Keywords:** Apple, Chemical Thinning, Hormones, Thinning,

#### INTRODUCTION

The cultivated apple "*Malus x domestica* Borkh", which is an interspecies hybrid complex in the genus *Malus*, is an important fruit species recognized all over the world. The oldest archaeological remains of apples found in Anatolia, dating back to 6500 BC, show that this species has been known by humans for thousands of years (Luby 2003). Apple, a type of temperate climate fruit, is currently cultivated in a large number of countries (Özçağiran *et al.* 2011).

86 million tons of production were made according to the data of the world apple production year 2020. China ranked first with a production of 41.5 million tons, while the USA ranked and Turkey ranked second and third respectively with 4.84 million tons and 3.96 million tons (Anonymous 2022). When we look at the apple production areas of Turkey, Niğde ranks first with 235 thousand decares of orchards in 2019. When we look at the number of apple trees in the yield age, Karaman Province is one of the leading other provinces with 9.2 million trees. The provinces of Niğde, Isparta, Karaman, Antalya, and Konya constitute about 52% of the total apple production areas of Turkey with a production area of about 912 thousand decares. China and the USA, which are in the first places in terms of the amount of apple production, are in the top places as the largest exporters of the world in the apple export ranking. Although Turkey ranks 3rd in world apple production, it ranks 14th behind many countries in world apple exports (Anonymous 2022). Apple cultivation should be carried out with varieties that are accepted all over the world and modern practices and techniques that will increase quality production in these varieties should be given importance in order to improve the current situation in Turkey. The interest in different tastes and flavors in apples, as in other fruit types, especially in developed countries such as Russia, Germany, England, and the Netherlands, which are leading in apple imports with high-income levels, causes varieties with these characteristics to come to the fore in cultivation in countries with high export values (Dousti and Dumanoğlu 2011).

Fruit quality is affected by many factors such as genotype, climatic conditions, rootstock and variety characteristics, soil structure, location and direction of the garden, irrigation water and distribution, fertilizer type and application time, dilution, and pruning. 'Thinning' is one of the main cultural processes that positively affects the quality of apple varieties, especially in many fruit types and varieties. Thinning is the process of

removing flowers and small fruits on the plant from the plant, reducing the amount of fruit and lightening the product load (Karakuş and Kalyoncu 2011; Kaşka 2003).

Growers need to obtain proportionally more large and colorful fruits from their orchards in order to be able to produce in the competitive conditions required by domestic and foreign markets in apple cultivation. In other words, it has become important for producers to produce fruits of "marketable" quality (Çağlar and Balcı 2003). Thinning is especially important for apple species. If all cultivating processes are performed appropriately but without thinning, it may not be possible to obtain fruits of the desired quality due to excess fruit retention (Akgül 2004). The fruits become bigger, homogeneous and the shell color develops fully in the production of apples with the help of dilution. Branch breakage is prevented and the tendency of the periodical is reduced as a result of providing a balanced product distribution in the tree. In addition, struggling against diseases and pests is getting easier, and the costs of harvesting and post-harvest classification are decreasing (Butar *et al.* 2016; Kaçal 2009; Barritt 2000).

Manual thinning of fruits is a simple technique known since ancient times and used by manufacturers. Today, chemical thinning is indispensable for producers in order to save costs and labor in commercial apple cultivation. These chemicals used in thinning are used as substances produced by plant cells or synthetically produced substances. Plant growth regulators are substances that stimulate, inhibit, or otherwise change physiological functions in organisms (Morsünbül 2010; Güllüoğlu and Arioğlu 2005). Many plant growth regulators are used to improve the quality and yield in the production of agricultural products. Plant growth regulators are examined in five main groups according to their structures: auxins, gibberellins, cytokinins, dormins (abscisic acid), and ethylene (Yerlikaya 2008). In our country, which is an important apple producer, not much work has been done on fruit thinning and methods. Therefore, our article titled "Investigation of fruit thinning methods used in apple species" is important from this point of view.

### **Apple Flower Structure**

Fruit quality in apple species arises as a result of the mutual relationship of grower practices such as pruning, other cultivating processes, and product load management with environmental factors other than plant genetic structure. In addition to product quality, it is important to be able to produce regularly every year in order to recover costs and maintain competitive power (Bound 2005). The apple plant forms flowers on short fruit branches (bouquets). There are about 5-6 flowers in each beam on the bouquet. The flower is located in the middle of this 5-point flower structure and the earliest blooming flower is called the "king flower", and the others are called the "side flower". In some cases, all flowers are pollinated, then fertilized, and fruit retention increases. Depending on climatic conditions, pollination success, and the age of the tree. 8-16% of blooming flowers should be fruit for fruit set with high quality and market value. Fruit weight and fruit size are negatively affected in trees with a large amount of product, therefore fruit quality decreases (Mcafee 2006; Salvador *et al.* 2006; Çağlar and Balcı 2003).

### **Manual Thinning**

Although manual thinning is the most reliable method, it is not economical in commercial production due to high labor costs (Janoudi and Flore 2005). In weather conditions where the risk of late spring frost is minimized, it is recommended to do manual fruit thinning after the product load is clearly determined. The distribution of fruits on the tree will also be monitored in this period and thinning will be performed accordingly, which will provide significant advantages to the producer. Manual thinning is a preferred method due to the fact that it is not a harmful application to the environment and the fruits are removed from the tree in a controlled manner. The most important disadvantage of manual thinning is that it increases labor costs (Demircan *et al.* 2005; Webster 2002). Some growers expect the thinning application to yield small fruits the size of walnuts. However, since the thinning process is so delayed, it will not be possible to reach the expected target as long as the fruits remain on the tree since they use the tree's food sources. In other words, thinning made at an early stage contributes more to the growth of fruits. Apple variety characteristics should be taken into account when making manual thinning. Varieties with strong tree growth could leave two fruits per beam, whereas varieties with weak growth should have left one fruit (Caglar and Balcı 2003). In general, in apple cultivation, reducing the number of fruits to 4-6 fruits in the trunk cross-section area in order to achieve good fruit quality and size, and arranging this amount to 5 fruits in the trunk cross-sectional area in the varieties showing periodicity ensures the optimum success of dilution (Robinson 2008; Robinson and Watkins 2003).

The thinning process can be done manually very simply and reliably by hand in apple species. Considering that manual thinning requires a lot of labor and labor wages increase production costs in today's conditions, it is not a preferred method in commercial gardens. This method is mostly applied in small gardens or as a complement to chemical thinning. Therefore, thinning with chemicals is mainly preferred in today's commercial apple cultivation (Caglar and Balci 2003).

### Chemical Thinning

Thinning with chemical substances reduces the labor requirement and provides the possibility of use in large areas. Post-flowering thinners are used commercially in apples. Chemical thinners can be used at different phenological stages to dilute buds, flowers, or small fruits. However, reducing the buds before flowering is a risky practice due to the winter cold and late spring frosts, and its practical use is not widespread (Layne 2007; Janoudi and Flore 2005; Fallahi *et al.* 2004). Hormones are organic substances that can be synthesized and transported in plants, guide the growth and development events in plants, and can be effective even at very low changes. These substances are obtained from the organs of many plant species and some fungi. Hormones produced in some cells are transported to other cells and development is controlled. These natural and synthetic substances that have been determined to affect plant growth and development are called plant growth regulators. Plant growth regulators cause various physiological reactions in the plant (Kumlay and Eryigit 2011; Aydođdu and Boyraz 2005). Plant growth regulators are divided into two main groups due to their stimulating and retarding properties on plants; those that initiate and accelerate plant development are called (stimulants), and those that slow down and stop growth and development are called (inhibitors). Among them are those that have a stimulating effect on the plant; auxins, gibberellins, and cytokinins. The plant growth inhibitors are abscisic acid (ABA) and ethylene (Morsünbül 2010; Karakaya and Padem 2009). Synthetic hormones, which we call plant growth regulators, are widely used in garden plants for various purposes. For this purpose, Carbaryl (Sevin), a broad-spectrum insecticide, is often used alone or mixed with chemical substances (NAA, NAAM, BA) in small fruit thinning. In recent years, it has been determined that some other chemicals, such as Hydrogen Cyanamide, Etefon, and Thidiazuron, have thinning properties. Small fruit thinning is more common than flower thinning in modern apple cultivation (Karakaya and Padem 2009). The thinners used in the flower thinning process damage the floral organs, preventing pollination or fertilization and therefore reducing the fruit attitude. Small fruit thinners are taken up by the fruit, they inhibit the growth of the fruit, causing shedding. The level of thinning in apple species is greatly influenced by various factors such as the dose of the chemical used and the spraying time, the physiological state of the tree, the cultivation system, the variety, rootstock, and cultivating processes, as well as environmental conditions (Fallahi and Wilemsen 2002).

### Auxins

Auxin-type plant growth regulators are hormones that have been used in agriculture for a long time. It is the most important group that affects the growth and development of plants. It performs the growth of the plant together with other plant growth regulators. It is naturally rare in the plant root. Auxins are synthesized in meristematic tissues such as leaves, apical buds, and flowers and are transported from top to bottom. It ensures the growth of the plant. It regulates cell division, and cell and tissue differentiation. It allows the plant to grow toward the sun (Algül *et al.* 2016). Auxins are studied under 4 groups and their important growth regulators are as follows. a) Indole group b) Naphthylene group c) Phenoxy group d) Benzole group (Baktir 2010). It stops growing when too much is secreted by the plant or when administered in high doses in artificial forms. When it reaches low levels in the plant, it causes the leaves to fall out. It is effective in fruit set and formation. Prevents fertilized flowers from falling. It ensures the development of the ovary and the formation of seedless fruit. Regulates the development of cambium in spring. Artificially obtained auxins are usually used in weed control. Some of these chemicals are known as 4-CPA (4-chlorophenoxyacetic acid), 2,4-D (2,4-dichloro phenoxy acetic acid), IAA (indol acetic acid), IBA (indolbutyric acid), and NAA (1- Naphthaleneacetic acid) (Karakuş and Koker 2007; Halloran and Kasim 2002).

### **NAA (1-Naphthaleneacetic acid) and NAAM (Naphthalen Acid Amide):**

NAA and NAAM, which are auxin-type thinners are widely used effectively in apples. These hormones are absorbed from the leaves and form the separation layer by promoting the formation of ethylene so that fruit falls are performed (Gadner 2003). The chemical structure of 1-Naphthaleneacetic acid (NAA) is  $C_{12}H_{10}O_2$ . Today, various formulations are available on the market in the form of ammonium, potassium, sodium salts, or ethyl esters. 1-Naphthaleneacetic acid, a plant growth regulator, is available on the market as a solid, white, odorless, tasteless substance with a molecular weight of 186.2 g/mol. May show chronic damage to the lungs when inhaled. It causes serious hazards in case of skin contact, inhalation, and ingestion. NAA promotes elongation and root formation in plants. However, its use in high concentrations has a growth-inhibiting effect. This chemical is in the toxicity level 3 class According to the data of the World Health Organization (WHO) and the Environmental Protection Organization (EPA) (Çetinkaya and Baydan 2006). 1-Naphthaleneacetic acid (NAA), especially for dilution in apples, pears, and olives, gives successful results when applied during the period when 70-80% of flowers are blooming. It is recommended to carry out the applications after the danger of late spring frost has passed, in order to guarantee the products. It is usually used for thinning in apples at concentrations of 2.5-20 ppm. As the dose of NAA used increases, the amount of thinning also increases. However high doses of NAA both damage the leaves and cause small fruit formation (the fruit remains on the tree without growing). Therefore it is emphasized that the use of high doses of NAA should be avoided. It will be better and faster for NAA prepared quite homogeneously in water to be taken up by the leaves. Emissive and adhesive substances should be added to the solution to increase the absorption effect from the leaf surface. Spraying is in the warm and windless morning hours when hormone uptake is highest and slow drying conditions are provided. NAA is not effectively applied in conditions where the air temperature is below 10°C. It is recommended to apply NAA 7-14 days before harvest to prevent pre-harvest fall in apples and pears. NAA applied to the plant shows its effect 2-3 days after application and its effect continues for 2 weeks (Baktır 2010; Halloran and Kasım 2002).

### **Ethylene**

Ethylene, a simple compound produced by plants ( $C_2H_4$ ), has been known for many years as a highly effective plant growth regulator in gaseous form (Westwood 1993). Ethylene synthesis may vary depending on environmental factors (Seçer 1989). Ethylene can be produced in all plant tissues. Ethylene is mostly synthesized from mature and aging tissues under stress. Leaves and flowers synthesize the highest amount of ethylene in the period before wilting and falling. The least amount of ethylene is synthesized by the roots of the plant. It is gaseous, volatile, and partially inactive under normal conditions. It is a hormone that can be produced by the plant at every stage of plant growth and development. Also known as maturation hormone (gas). Ripening, quality losses, aging, and deterioration of products occur faster due to ethylene secretion in fruits and vegetables in warehouses with insufficient ventilation (Baktır 2010; Kumlay and Eryiğit 2011). The effect of ethylene in these changes affects metabolic events such as the degradation of the chlorophyll structure and the synthesis of other pigments, the breakdown of the cell wall and the softening of the fruit, the synthesis of volatile compounds that make up the fruit smell, an increase in respiratory rate, and the conversion of starch into sugar (Öktüren and Sönmez 2005). In addition, the different effects of ethylene on plants are as follows; breaking dormancy, falling leaves and fruits, promoting flowering in some plants, stimulating adventitious root formation, encouraging female flower formation in monoic plants, and facilitating mechanical harvesting by encouraging abscission (Algül *et al.* 2016).

### **Cytokinins**

Unlike other hormones that occur especially during cell division in plant tissues, quinine is an organic substance found in both plants and animals. The first plant-based cytokinin was zeatin, which was isolated from corn seeds. Zeatin, dihydrozeatin, isopentenyl adenine (2IP), and dimethylallyl adenine are naturally synthesized cytokinins, kinetin (N<sup>6</sup> furfuryl amino purine), benzyl adenine (BA) and tetrahydropyranlylbenzyl adenine (PBA) are synthetic cytokinins (Üstün *et al.* 2010). The physiological roles of cytokinins in plant tissues; cell division and organ formation are their effects on cell growth. All tissues with active cell division contain a high amount of cytokinins. Cytokinins are effective in cell division and have a function in tissue and organ differentiation. They also play an active role in such formations as chlorophyll breakdown and aging retardation, flower stimulation, frost resistance, seed germination, parthenocarpic fruit formation, gender differentiation, fruit attitude and fruit growth, and side bud development. Protein and RNA synthesis and

enzyme activity are other main activities in which cytokinins are effective. Cytokinins are usually found in young tissues. It is synthesized especially in the root meristems and then transported to the green parts of the plant through the xylem. Auxins support root formation, while cytokinins support shoot formation. They contribute to the formation and development of organs in tissue-cultivating environments (Dodd 2003; Karakaya and Padem 2009; Baktır 2010; Kumlay and Eryiğit 2011).

## Giberlin

Giberlic acid, which is one of the growth and development-promoting hormones, was first found in 1926 by Japanese researchers in the fungus *Gibberella fujikuroi*, which causes over-sizing in rice plants and takes its name from here. Later, this substance was isolated and named giberelic acid (GA) (Kılıç 2007; Morsünbül 2010). The most commonly used type among gibberellins is GA. It is known that there are at least 126 different species of gibberellin today. Gibberellin is found in large quantities in the buds, embryos, roots, young leaves, flowers, fruits, and cambium of plants. Only the GA type is commercially available and important Among the gibberellins (Baktır 2010). The most obvious effect of gibberellins is to increase the elongation of cells. Moreover, they are very effective in breaking seed and bud dormancy, eliminating stunting, meeting the need for cooling, parthenocarpic fruit set, and promoting germination. GA is mainly used in table and dried grapes to thin the bunches and increase the grain size (Tyler *et al.* 2004; Olszewski *et al.* 2002).

## CONCLUSION

The thinning process has been recognized as one of the cultivating processes that should be paid attention to in many fruit types, especially apples, in recent years. When thinning is done correctly and on time, it causes an increase in fruit quality, especially in fruit size, color, taste, and many other parameters. In addition, thinning eliminates periodicity in fruit trees and ensures that a regular crop is obtained every year. Although manual thinning provides high success in apple species, this process is not preferred in large orchards and commercial production enterprises because it requires labor costs and a very long time. Chemical thinners that are more cost-effective and can be applied evenly in a short time are preferred in such large and high-production enterprises. Although chemical thinning is applied more easily and quickly than mechanical dilution, considerations such as the dose and time of administration of the drug, the age of the trees to be applied, and the suitability of the thinner for the flowering period or small fruit period should be considered. Any negligence or fault in chemical dilution can cause irreversible damage.

#### Abstract

As a result of the intensive use of biotechnology in cattle breeding, the incidence of rare genetic defects in the population has started to increase. Studies have focused on identifying cattle with hereditary defects using molecular methods. It is important to identify the carrier cattle in order to reduce genetic defects in subsequent generations. Brachyspina Syndrome (BS) and Cholesterol Deficiency (CD) had been identified in a previous study in Holstein Friesian cattle in Turkey. With regard to these two hereditary defects, in the study conducted to investigate samples were taken from the Holstein Friesian cattle reared in Eskişehir by using PCR technique. 3 and 11 cattle were found to be carriers of the BS and CD, respectively, among 112 Holstein Friesian cattle. The possibility of the spread of genetic defects and economic damage can be prevented using molecular techniques. The herds that are free of genetic defects be created by using some molecular methods detecting hereditary diseases, and by planning creation of new generations.

**Keywords:** ABOP genes, Brachyspina Syndrome, Cholesterol Deficiency, FANCI genes, Holstein

#### 1. Introduction

Hereditary diseases in cattle can cause significant economic damage. These diseases are very difficult to detect. Today, with the development of technology, there are new hereditary diseases. One of them is "Cholesterol Deficiency (CD)", which is recessive and hereditary and was discovered in 2015, and the other is "Brachyspina Syndrome (BS)", which was first discovered in Denmark in 2006 (Özcan and Özbeyaz, 2017).

For autosomal recessive diseases to occur, functional changes must occur in both pairs of genes at the same location. This type of hereditary disease does not show up in every generation. Most known hereditary diseases in cattle are caused by autosomal recessive alleles. However, autosomal recessive alleles spread within the population because they are not seen in the external appearance and therefore cannot be identified if the animal shows heterozygous inheritance (Agerholm, 2007). According to OMIA, the total number of diseases found in cattle is 630 (OMIA, 2023). 73 of these diseases are found in the Holstein breed (OMIA, 2023).

Brachyspina syndrome first appeared in 2006 (Agerholm et al., 2006). To date, it has been found in the Netherlands (Agerholm and Peperkamp, 2007), Italy (Testoni et al., 2008), Germany (Buck et al., 2010) and Canada (Agerholm et al., 2010). Brachyspina syndrome is a rare hereditary defect in Holstein cattle. The mutation that causes Brachyspina Syndrome is located on the FANCI gene (OMIA, 2023). The disease is caused by a 3329 base pair deletion in the Fanconi anaemia complementation group 1 (FANCI) gene, which is located on the 21st chromosome of the bovine chromosomes (Charlier et al., 2012). While the FANCI gene normally contains 37 exons, the mutation results in a frameshift deletion from exon 25 to 27, creating a stop codon in exon 28 (Li et al., 2016). After the first two cases, two calves were stillborn in Italy and the cause was brachyspina syndrome. As in the first case, these two stillborn calves also had long legs and short bodies. Various abnormalities were also observed in the autopsy findings examined radiographically (Testoni et al., 2008). Apart from these cases, dead Holstein Friesian calves with identical phenotype and morphological signs were reported in the Netherlands (Agerholm and Peperkamp, 2007), Germany (Buck et al., 2010) and Canada (Agerholm et al., 2010). In Poland, when 78 Holstein peregrine cattle were examined by Ruśc and Kamiński (2015), 8 out of 78 animals were found to be carriers. In China, when 342 peregrine falcons born between 1996 and 2012 were screened by Li et al. (2016), 13 of them were found to be carriers. Chao et al.

(2020) randomly identified 1688 cattle from herds in northern, central, southern and eastern Taiwan. In the first study conducted in Turkey, 250 Holstein Friesian cattle were tested for BS in 2021 and 1 cattle was found to be a carrier. These results of the study showed that this hereditary disease is also present in Holsteins reared in Turkey, even at low frequencies (Bedir Dibic, 2021).

The hereditary defect of cholesterol deficiency was first encountered in a bull named Mauglin Storm, born in 1991 (Menzi et al., 2016). As bulls descended from Mauglin Storm are used in artificial insemination, the frequency of the mutant allele causing the hereditary defect of cholesterol deficiency has increased in many countries. Calves with homozygous inheritance of the defect showed signs of hypolipidaemia and hypocholesterolaemia. It has been called cholesterol deficiency, which is also expressed as an autosomal recessive genetic defect and genetic lipid metabolism disorder in calves, resulting in death (Kipp et al., 2015). Cholesterol deficiency results in a 1.3 kb insertion in the 5th exon of the apolipoprotein B (APOB) gene on the 11th chromosome of *Bos Taurus* that affects lipid metabolism and results in early death (Schutz et al., 2016). APOB is the structural chylomicron protein of low (LDL) and very low (VLDL) density lipoproteins (Kane et al., 1980). The resulting 1.3 kb insertion creates a stop codon in the open reading frame (ORF) of APOB. As a result, the protein region is much shorter than its 140 amino acid length. In relation to this genetic disease, animals with heterozygous inheritance often have no symptoms, while this hereditary defect is encountered in some way at an advanced age. In animals with homozygous genotype in relation to cholesterol deficiency; It has been observed that excretion of chylomicron in the intestine cannot be made at an early age, but it has been shown that there is a problem in the cholesterol absorption stream (Schütz et al., 2016). Looking at the studies on CD, 27 Holstein Friesian cattle in Poland were selected by studying the Mauglin Storm pedigree, and 9 cattle were found to be carriers of the hereditary cholesterol deficiency disease. These results suggest that the mutation causing the genetic disease CD is also transmitted to Holstein cattle in Poland (Kamiński and Ruśc 2016). In Switzerland, a study was conducted on the effect of the ABOP genotype on cholesterol metabolism in 254 Holstein cattle. As a result of the study, no homozygous alleles were found in 254 Holstein cattle, 36 Holstein cattle were carriers and 218 Holstein cattle had normal alleles. Of 1817 randomly selected Russian cattle born in Russia between 2010 and 2017, 147 were found to carry the defect. In order to carry out a study on this disease in domestic cattle and Holstein breeds bred in Turkey in 2021, 250 migratory animals were examined. As a result of the study, 4 cattle out of 250 were found to be carriers. These results of the study showed that this hereditary disease is also present in Holstein-Friesian cattle bred in Turkey, although at a low frequency (Bedir Dibic, 2021).

The genetic defects of Brachyspina Syndrome and Cholesterol Deficiency, which have been identified in cattle populations in different countries, were investigated using samples from the Holstein cattle population reared in Eskişehir. With this research, these two genetic defects in the Holstein breed, which is often preferred in dairy cattle breeding in Eskişehir, were investigated using the PCR method and it was aimed to benefit from healthy herds.

## Material and Methods

This study was carried out at Eskişehir Osmangazi University, Faculty of Agriculture, Department of Agricultural Biotechnology, Molecular Genetics Laboratory. This research includes the steps of isolating the genomic DNA molecule from the blood samples, amplifying the regions related to hereditary defects by PCR, and interpreting the base pairs formed by the PCR products in terms of hereditary defects.

### Material

DNA was purified from blood samples collected from 112 animals from 4 different Holstein farms in Eskişehir. Genomic DNA was isolated from the blood samples using the Thermofischer DNA isolation® kit and stored at 4°C.

### Methods

In the study, blood samples from 112 animals were stored in 5ml EDTA tubes at -20°C until DNA isolation. DNA isolation was from blood using commercial kits (PureLink DNA isolation® genomic DNA isolation kit). After DNA isolation, DNA samples checked in agarose gel.

The genotypes for BS and CD were identified by using PCR method. The PCR reaction mixture (20 µl) contained 50–100 ng DNA template, 10X Taq polymerase buffer, 1.5 mM MgCl<sub>2</sub>, 2.5 mM dNTPs, 0.5 U Taq DNA polymerase and 5 pmoles of each primer (Table) per reaction. The PCR cycle profile was 94°C for 3

minutes; then 35 cycles of 94°C for 15 sec., 58°C (BS) and 65°C (CD) for 20 sec., and 72°C for 30 sec; followed with 10 minutes at 72°C. PCR products were run by electrophoresis using 2% agarose gels. Primers for BS, ATP8 and CD related gene regions are shown in Table.

**Table 1.** Gene regions related to BS, ATP8 and CD

	Primer sequence	Fragment size	Literature
<b>BS</b>	F: 5' GCTCAAGTAGTTAGTTGCTCCACTG3'	409 bp	Li, Y., et al., 2016
	R: 5' ATAAATAAATAAAGCAGGATGCTGAAA3'		
<b>ATP8</b>	F-W: 5' TAAGTTAGAGATTGAGAGCC3'	269 bp	
	R-W: 5' GATAAGGGTTACGAGAGGGA3'		
<b>CD</b>	Forward-W: 5'GGTGACCATCCTCTCTCTCTGC3'	436 bp	Menzi, F., et al., 2016
	Reverse: 5'AGTGGAACCCAGCTCCATTA3'		
	Forward-M: 5'CACCTTCCGCTATTTCGAGAG3'		

## Results

DNA samples obtained from 112 Holstein cattle in the study population were run on a 1% agarose gel. The image of the DNA samples after electrophoresis is shown in Figure 1.

**Figure 1.** Image of some DNA samples to be used after electrophoresing using 1% agarose gel electrophoresis

PCR for Brachyspina Syndrome were visualised on a 2% agarose gel. As a result of the band pattern, 2 heterozygous individuals for the BS were detected among the cattle studied. According to Li et al. (2016), The ATP8 gene is used for PCR accuracy due to the positive control. Therefore, 269 base pairs were observed in the PCR results of all healthy and affected cattle in BS genetic defect.

**Figure 2.** Detection of BS genotypes by 2% agarose gel electrophoresis of BS genotype expressions. 2. well and others; normal genotype (269 bp); M:100 bp ladder, Fermentas® GeneRuler SMO241

**Figure 3.** Determination of BS genotypes by 2% agarose gel electrophoresis of BS genotype expressions. 12. well ; Heterozygous genotype (269 and 409 bp) found in Holstein cattle; M:100 bp ladder, Fermentas® GeneRuler SMO241

**Figure 4.** Detection of CD genotypes by 2% agarose gel electrophoresis method. wells 7 and 13 normal genotype (269 bp); wells 1 and 2 are heterozygous genotypes (249 and 436 bp) found in Holsteins; L:100 bp ladder, Fermentas® GeneRuler SMO241

In CD carrier and animals, 409 base pairs were also observed due to the mutation. Menzi et al, (2016) found that 249 base pairs were observed in healthy cattle in relation to the CD genetic disease. As a result of the visualisation process, 11 heterozygous individuals were found among the cattle studied in terms of cholesterol deficiency.

Following the PCR studies conducted in Eskişehir, it was found that two out of 112 Holstein Friesian cattle were affected by Brachyspina syndrome. Additionally, the deficiency allele for cholesterol was present in eleven of them. The mutant allele frequency of CD and BS was estimated 0.0491, and 0.0089 respectively.

## Conclusions

Predicting genetic disorders in animal husbandry and ensuring population health through controlled breeding is a vital concern. It is crucial to detect heterozygous animals to manage genetic diseases in animal populations and mitigate risks by conducting a pre-breeding examination of the cattle intended for breeding. This approach will preserve the health of the future population and prevent any adverse impact on yield.

After the existence of the identified cases in Turkey (Bedir Dibic, 2021), the identified population in Eskişehir was also examined in a special framework with regard to BS and CD hereditary diseases and the existence of the diseases was determined.

By knowing the frequencies of these two hereditary diseases which directly affect the yield in the population, the cattle to be used as breeding stock in the future population can be known, which will prevent the direct decrease in yield by providing disease control.

As a result of this study, it was found that 2 cattle for BS genetic defect and 11 cattle for CD genetic defect were heterozygous genotype in Holstein cattle population in Eskişehir. Breeding selection in the formation of future populations by paying attention to these data will reduce the frequency of these hereditary diseases.

#### Abstract

Nowadays, people spend most of their daily time ( $\approx 90\%$ ) indoors. Particulate matter is among the most important pollutants affecting indoor air quality. Indoor air quality is directly affected by indoor PM<sub>10</sub>. Short and long-term exposure to PM<sub>10</sub> can cause serious harm to human health. Most people dedicate a minimum of two days a week, with each day comprising at least one hour, to private gyms. In this study, measurements of indoor and outdoor PM<sub>10</sub> concentrations were conducted at a private gym in Eskişehir. The measurements were taken during various training intensities, including light, medium, and heavy workouts, as well as during hours when the students were not engaged in training. When comparing the measurements to the indoor PM<sub>10</sub> limit value set by the USEPA (American Environmental Protection Agency) at 150  $\mu\text{g}/\text{m}^3$ , it was observed that PM<sub>10</sub> levels exceeded this limit when the balcony door was opened to ventilate the indoor environment, both during heavy training sessions and during non-training hours. It was noted that PM<sub>10</sub> levels did not exceed the limit value during medium and light training hours. On days characterized by heavy training sessions and poor outdoor air quality, indoor air quality poses a potential risk to both trainers and students. This underscores the significance of enhancing indoor air quality during these specific hours.

**Keywords:** Indoor Air Quality, PM<sub>10</sub>, Private Gym

#### INTRODUCTION

In recent years, Indoor Air Quality (IAQ) has received increasing attention from the international scientific community, political institutions and environmental governments to improve the comfort, health and well-being of building occupants. Numerous studies on this topic have demonstrated both qualitative and quantitative shifts in indoor air quality (IAQ) over time, emphasizing the rise in pollutants and their concentrations. For this purpose, standards and regulations regarding IAQ, policies and monitoring plans for non-industrial buildings have been developed in various countries. It is known that people spend about 90% of their time in both private and public indoor environments such as homes, gyms, schools, workplaces, transportation vehicles. Therefore, IAQ has a significant impact on health and quality of life in general. For many individuals, the health hazards associated with indoor air pollution exposure may surpass those stemming from outdoor pollution. In particular, poor IAQ can be detrimental to vulnerable groups such as children, young adults, the elderly, or those suffering from chronic respiratory and/or cardiovascular diseases (Braleswska et al., 2022; Cincinelli and Martellini, 2017; Engel-Cox et al., 2013).

Particulate matter (PM) constitutes a primary focus in the study and control of air pollution (Dominici et al., 2014). Particulate matter includes both primary particles such as soot and dust from combustion sources and agricultural practices, and secondary particles such as sulfate and nitrate formed through chemical reactions from sulfur dioxide and nitrogen oxide in the atmosphere. The current focus is on PM<sub>10</sub> and PM<sub>2.5</sub>, which are particles less than 10 microns and 2.5 microns in diameter. Epidemiological studies of long-term exposure to ambient fine particulate air pollution have documented serious adverse health effects, including increased deaths from chronic cardiovascular and respiratory diseases, lung cancer, and adverse reproductive outcomes (Brunekreef and Holgate, 2002).

Indoor PM sources can be listed as smoking tobacco, burning wood and fossil fuels, burning candles and incense, cooking (especially frying and grilling), and cleaning (Zhang et al., 2021). Gyms typically do not

contain most of these resources. Key sources of particulate matter (PM) within gym environments include settled dust that becomes airborne due to the activities of gym members and emissions from vehicles in nearby parking areas, serving as an external source. The first of these is specifically PM<sub>10</sub> and the second is PM<sub>2.5</sub>. In contrast to semi-urban and rural settings, urban gyms near heavy traffic, gyms with a high member density per unit area, and city gyms during winter months exhibit higher levels of indoor air pollution. Additionally, rural areas experience increased pollution during summer months, while sports halls with inadequate cleaning practices or excessive chemical use for cleaning also contribute to elevated pollution levels. Elevated levels of particulate matter have been detected in gyms, particularly in those where indoor air chemistry reactions, such as those involving ozone and terpenes, take place (Sofuoğlu, 2016).

The domains of sports and physical exercise encompass physical, psychological, and performance dimensions and are frequently conducted in indoor environments. The metabolic reaction to physical exercise places the body at a heightened risk of pollutant exposure, as the heightened respiratory ventilation rate during exercise leads to the inhalation of larger quantities of air and consequently, airborne pollutants. During exercise, individuals tend to inhale air through their mouth rather than allowing it to pass through the nasal filtering system. The amplified airflow rate carries pollutants deeper into the respiratory system, heightening the health risks to humans. This study assessed indoor air quality by quantifying particulate matter (PM<sub>10</sub>) levels within a private gym located in Eskişehir, Turkey.

## MATERIALS AND METHODS

### Study area and measurement points

The research took place from January 4, 2023, to January 6, 2023, encompassing the training hall, locker room, and outdoor area (balcony) of a private gym, situated in the Yenibağlar neighborhood of Eskişehir, Turkey. Figure 1 displays schematics of the gym where measurements were conducted, along with the device placements. Measurements were conducted on January 4th during medium-intensity training, on January 5th for both light and heavy training sessions, and on January 6th during unstructured free training periods.

The gym has a total area of 85.215 m<sup>2</sup>, including a locker room of 6.148 m<sup>2</sup> and a training area of 26.22 m<sup>2</sup>. There is no mechanical ventilation in the studio, ventilation is provided by air conditioning and windows. The gym's sole entrance and exit door remains closed at all times.

Two DustTrak II Aerosol Monitors were used for PM<sub>10</sub> measurements. One of the two devices employed was initiated in the locker room 15 minutes prior to the training session and relocated outdoors after 30 minutes, with measurements ongoing until 15 minutes post-training. The device positioned in the hall remained stationary throughout the study.

**Figure 1.** Drawing of the gym and locations of the devices

## Study Program

Concurrent measurements were conducted in both indoor and outdoor environments, and the performance of the two devices employed was assessed through parallel laboratory testing. The comparison yielded an  $R^2$  value of 0.97. This process affirmed the compatibility of the devices and validated their suitability for field measurements.

Measurements were conducted corresponding to the exercise intensity levels, encompassing inactive periods as well as light and heavy workouts, which took place in the locker room, training room, and outdoor areas. Typically, training sessions in the gym commence at the top of the hour and last for approximately 45 minutes. Upon arrival, students enter through the sole entrance and exit located in the hall and proceed to the locker room for changing into their workout attire. The duration of their stay in the locker room varies individually but averages around 5 minutes.

The initial measurement occurred during the 16:00-16:45 session, featuring intermediate-level training, with a focus solely on indoor environmental levels. The second measurement was conducted during the 08:00-08:45 session, with two individuals engaged in heavy training. The third measurement was carried out during the 13:00-13:45 session, with a single individual participating in light training. The fourth measurement occurred in the studio during the non-training session from 11:00 to 11:45. At that time, there were a total of three individuals present in the studio, and physical activity was minimized.

Also, I/O ratios were determined based on the results obtained from measurements conducted indoors and outdoors for all measurement points.

## RESULTS and DISCUSSION

### PM<sub>10</sub> Concentrations

On January 4, 2023, measurements were conducted within both the locker room and the training hall. The training session commenced promptly at 16:05, at which point the student departed from the locker room. It is noteworthy that all windows and doors remained tightly shut throughout the duration of the training. The training session itself initiated with a series of warm-up exercises employing lightweight equipment, followed by the incorporation of squats and plank movements. The student arrived at the locker room at 16:43, where they engaged in a series of exercises, including lateral pull-downs, leg curls, and concluded with a running session. After their workout, the student left the locker room. Based on the collected data, it was found that the impact of the student's mid-level training on the indoor air quality of the facility was minimal. Earlier in the day, the student had also visited the locker room briefly from 16:00 to 16:05 before heading to their class. Based on the collected data, it was observed that the concentration levels in the locker room were consistently higher than those in the training room. The highest concentration was recorded during the period when the student both entered and exited the locker room. Furthermore, an increase in concentration levels was noted after the student's entry into the locker room following their training session. The data obtained is given in Figure 2.

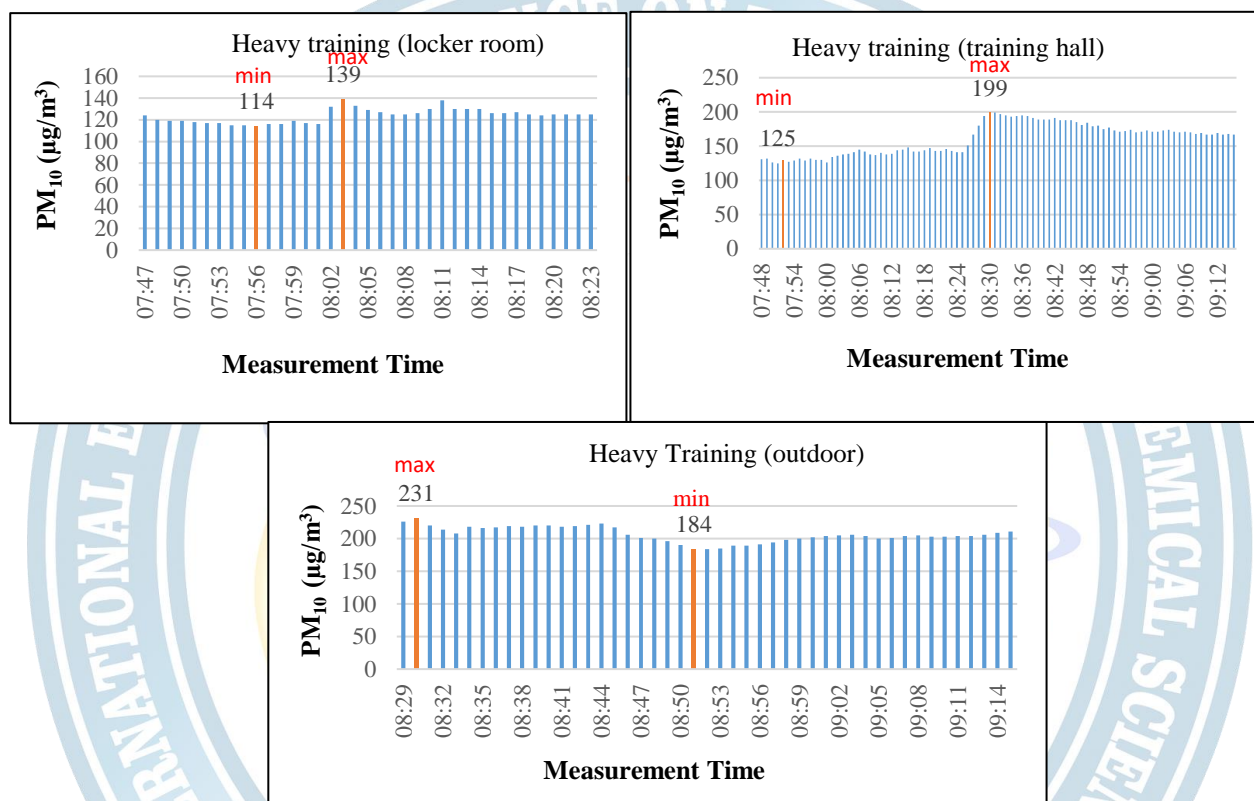

Figure 2. Medium training PM<sub>10</sub> concentrations

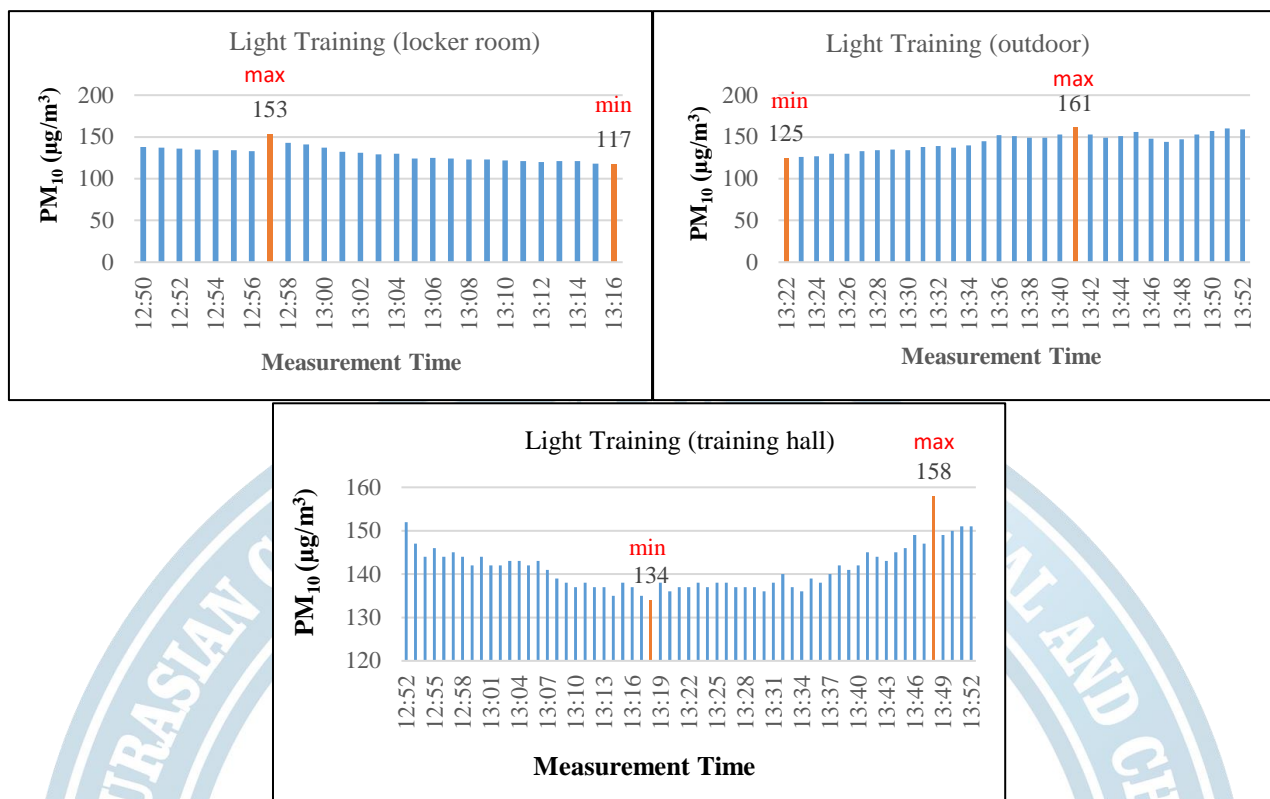

On January 5, 2023, a series of measurements were conducted during a rigorous training session in various locations, namely the locker room, outdoor environment, and the training hall. The students commenced their training in the locker room at 07:57, beginning with a treadmill and spinning workout. Subsequently, both students alternated between intense rope exercises, which involved strenuous movements like weighted jumping and jumping planks. The training persisted until the conclusion of the session at 08:58. The outdoor measurements were initiated at 08:24, with the balcony door being partially ajar throughout this period. The data analysis revealed a significant spike in PM<sub>10</sub> concentration, reaching its peak during the rope exercise session and the opening of the balcony door. Meanwhile, within the locker room, the highest concentration levels were recorded during the period when two students entered to use the facilities. Notably, concentrations outdoors consistently exceeded those indoors, indicating that external factors had the most pronounced impact on indoor air quality. The data obtained is given in Figure 3.

**Figure 3.** Heavy training PM<sub>10</sub> concentrations

On January 5, 2023, a set of measurements was conducted during a light training session encompassing the locker room, outdoor environment, and training hall. The training regimen predominantly involved the utilization of a reformer pilates machine in the hall. The training session concluded at 13:38. Notably, at 13:16, Device 2 was relocated outdoors and activated for data collection. It is worth noting that the initial concentration levels were elevated before the commencement of the training. However, these concentrations decreased during the course of the training and subsequently exhibited a gradual increase as the balcony door was opened. The lowest recorded air quality levels were observed during the training session, indicating that the light training had minimal impact on indoor air quality. Conversely, the highest levels were registered after the training when the balcony door was opened. Inside the locker room, the peak concentration occurred when students entered after the 12:00 class, gradually declining to its minimum during moments of inactivity when no individuals were present. In the outdoor environment, the measurements began at their minimum recorded levels and displayed a consistent upward trend over time. The obtained data is given in Figure 4.

**Figure 4.** Light training PM<sub>10</sub> concentrations

On January 6, 2023, a series of measurements were conducted in the locker room, outdoor environment, and training hall during a non-training period. The measurement session commenced at 11:10. At 11:29, Device number 2 was relocated from the locker room to the outdoors, where outdoor measurements were taken. Subsequently, the balcony door was left open. The measurement session concluded at 12:12. Initially, the air quality levels in the locker room were elevated, likely due to device preparation activities, but gradually decreased over time. In contrast, the changes in air quality levels within the training hall were minimal, but they reached their highest levels when the balcony door was open. This observed increase can be attributed to the outdoor environment being more polluted on the day of measurement compared to the indoor areas. The data obtained are given in Figure 5.

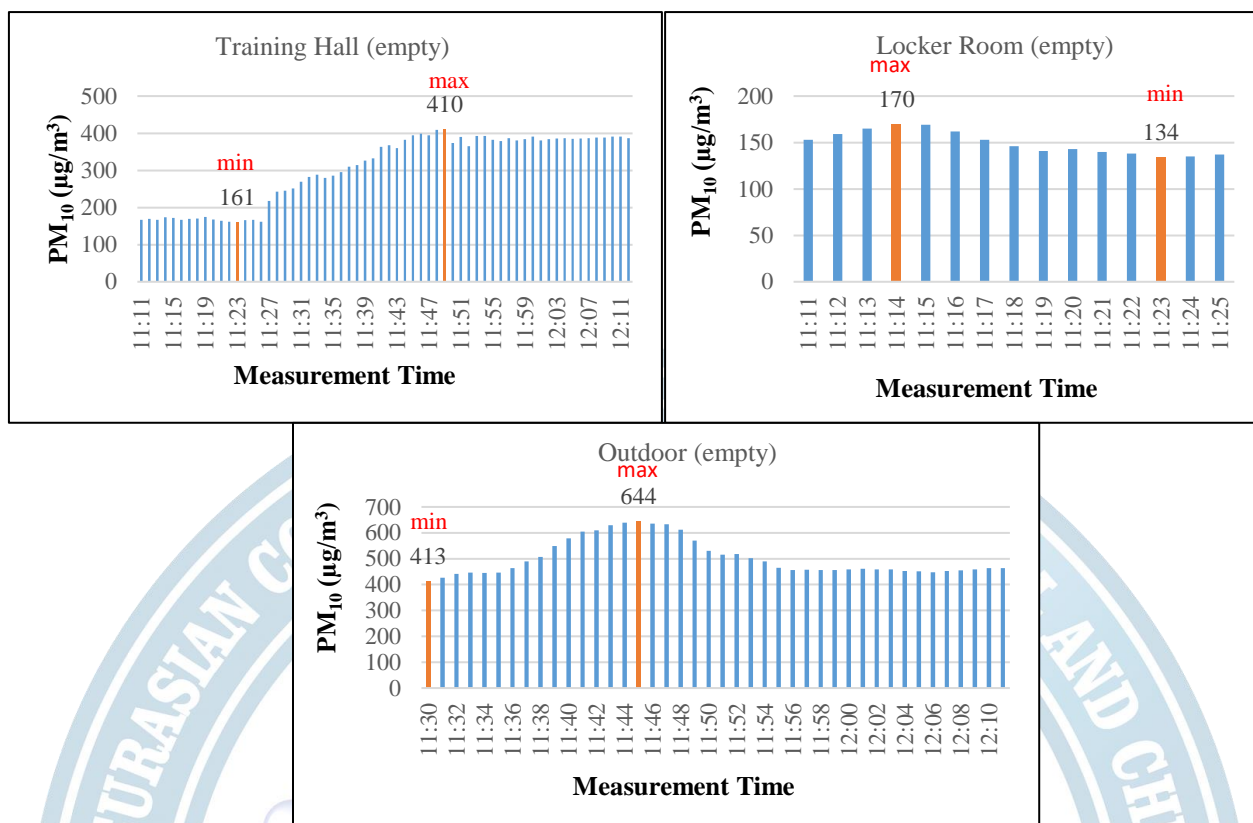

Figure 5. PM<sub>10</sub> concentrations during non-training hours

### I/O Concentration Ratios

Figure 6 presents the I/O ratio derived from concurrent measurements. When both the training hall and locker room are unoccupied, the I/O ratio is calculated at 0.72, which is below 1. A ratio below 1 signifies that indoor air quality levels remain lower than those of the outdoor environment when there is no activity within the indoor environment. In the context of light training, an examination of the I/O ratio reveals a value close to 0.98, approaching 1 but remaining slightly below it. This observation indicates that during light training, indoor PM<sub>10</sub> concentrations experience an increase compared to an empty hall; however, they still remain somewhat lower than the levels outdoors. This underscores the fact that the influence of the outdoor environment on indoor air quality surpasses the impact of light training activities. Upon examining the I/O ratio during heavy training, it becomes evident that this value exceeds 1, indicating that the impact of heavy training on indoor air quality surpasses that of the outdoor environment.

### CONCLUSION

Given the absence of nationally defined limit values for indoor air pollutants, a comparison is made between the average measured concentrations and the indoor PM<sub>10</sub> limit set by the USEPA (United States Environmental Protection Agency), which stands at 150 µg/m<sup>3</sup>. The data indicates that the measured values within the locker room consistently fall below this limit value across all training intensities and during unoccupied hours.

**Figure 6.** I/O Concentration Ratios

Upon examining the average values within the training hall, it becomes evident that the limit value was not exceeded during medium and light level training sessions. However, during heavy training and during unoccupied hours when the balcony door was open,  $PM_{10}$  concentrations exceeded the limit values, measuring at  $160.94 \mu\text{g}/\text{m}^3$  and  $305.77 \mu\text{g}/\text{m}^3$ , respectively. This circumstance underscores the risk posed to coaches and students due to the influence of polluted air resulting from heavy training and external sources on indoor air quality. Clearly, measures must be taken to enhance the indoor air quality within this environment.

Short-term exposure to indoor air pollutants can lead to discomfort, including symptoms like headaches, throat irritation, and fatigue. Conversely, prolonged exposure to these pollutants poses more severe health risks, including the development of conditions like heart disease, respiratory ailments, and even cancer. Owners of private gyms should prioritize the provision of a healthier indoor air quality for all individuals frequenting their facilities. Achieving this goal can be accomplished through proper ventilation systems that consider the outdoor air quality, thereby ensuring gyms are comfortable and safe environments for everyone.

#### ACKNOWLEDGEMENTS

We would like to thank Yurdaer Songer for his valuable support for allowing us to make measurements in his private gym in our study.

#### Abstract

**Introduction:** The increase in the number of patients with Diabetes Mellitus (type II) is closely related to the development of insulin resistance. This constitutes an international problem that requires special attention from the laboratory point of view and community awareness for recognizing risk factors that increase the risk of insulin resistance.

**The purpose of this study** is to identify whether lifestyle is a risk factor for possible insulin resistance and consequently for the development of type II diabetes mellitus after the Covid 19 pandemic.

**Materials and methods:** A random sample of forty-four students aged 18-22 living in the city of Tirana, who had different lifestyles, was selected to fill out a form with qualitative, evaluative data on lifestyle (physical activity, consumption of cigarettes, type of electronic or regular cigarette, family history of diabetes, concomitant pathology). For each member of the sample, the blood sample (serum) was examined for two parameters: fasting blood glucose and triglyceride. Based on these parameters, the TyG Index was calculated.

**Results and discussions:** 22 males and 22 females were included in the study.

- The ratio of cigarette users and non-users was 24/20 respectively.
- The ratio between normal body mass index (BMI) and abnormal BMI was 33/11 respectively.

Statistical processing with SPSS version 21 resulted:

- There is a statistically significant relationship between TyG and BMI ( $p=0.000$ )
- There is a statistically significant relationship between TyG and cigarette consumption ( $p=0.000$ )
- There is a statistically significant relationship between TyG and the daily amount of cigarettes smoked ( $p=0.000$ )
- There is a statistically significant relationship between TyG and alcohol ( $p=0.000$ )
- There is a statistically significant relationship between TyG and physical activity ( $p=0.000$ )
- There is a statistically significant relationship between TyG and medications ( $p=0.000$ )

**Conclusions:** Cigarette smoking, physical activity, alcohol and medications can be classified as independent risk factors for insulin resistance. Based on the results of the study, it is recommended to carry out other studies with a larger number of samples to better understand the role of each factor in increasing the risk of insulin resistance in order to make the population aware to avoid these factors. and to reduce the incidence of Diabetes in this age group.

**Keywords:** insulin resistance, BMI, cigarettes, alcohol, physical activity, Diabetes Type II.

#### Introduction

The increasing number of patients with diabetes mellitus (type II) is strictly correlated to the development of insulin resistance, which is the fundamental pathogenic component of many metabolic diseases, including type 2 mellitus diabetes, and is defined as a state of Reduced reactivity of insulin targeting fabrics to physiological insulin levels. (Lee et al., 2022). In recent years, it has been found that inflammation, the stress of the endoplasmic lattice and mitochondrial dysfunction, can promote insulin resistance (Gutiérrez-Rodelo et al., 2017) modifiable factors that are thought 'Insulin include diet, exercise, smoking, and stress. (Kelly, 2000) The two basic forces that spread insulin resistance are the increase in the consumption of caloric low food fast food and the decrease in physical activity due to mechanized transport and the sedentary form of temporal activities. (Saklayan, 2018). A life factor that can have direct and indirect effects on insulin resistance is cigarette smoke

(Artese et al., 2017). The prevalence of smoke of men and women aged 15 or over 15 in Albania, who currently smoke any tobacco product on a daily or non-daily basis for 2020 was 22.40% (Albania smoke rate 2000-2023, n.d.) except cigarette smoke, e-cigarettes are becoming very popular through young-adults. Electronic cigarettes (electronic cigarettes) are devices that can vaporize a nicotine solution combined with liquid flavours instead of burning tobacco leaves. (Rom et al., 2015) Electronic cigarettes are advertised aggressively as a help for the cessation of smoking; healthier, cheaper and more socially acceptable than conventional cigarettes (Rom et al., 2015). Therefore, the purpose of this study was to strongly refer to Jeong et al., 2021) should lay down the connection between lifestyle and insulin resistance in Aldent University students through the use of the Tyg index. The index of the triglyceride-glucose (Tyg index) is a marker of insulin resistance and metabolic dysfunction and has the advantage of being universally available (ZaIgham et al., 2022) and is greater than Homa-IR to predict type diabetes 2 (Park (Park. Et al., 2021). For these reasons, it is reasonable to evaluate the connection between lifestyle and insulin resistance using the Tyg index.

## Materials and methods

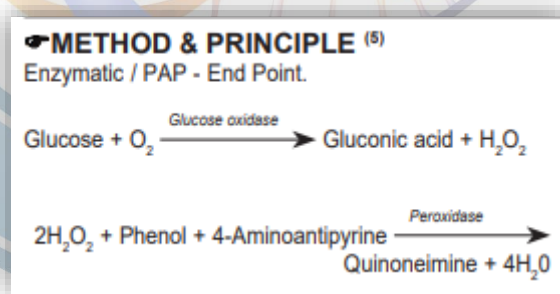

### The questionnaire

A random sample of 50 students from different departments of Aldent University has been selected to fill in a questionnaire with private data on lifestyle. The first part of this questionnaire suggested information on simple habits such as smoking, physical activity, alcohol consumption, personal and family history (including type II diabetes), age, height and weight and BMI, followed by the information part who requested the student's consent for performing phlebotomy.

### Laboratory tests

Information from participants diagnosed with chronic illness was excluded leading to performing phlebotomy to 44 individuals. In order to receive fresh serum samples. Blood was collected from forearm veins using a 21G vacuum system and centrifuged at 3000 rpm. Serum samples were examined for fasting glucose and triglyceride levels. A total of 10ul serum samples was mixed with 1000 glucose reagents (product #:21-0672, GPSL-0507, ELITEch Clinical system, France) Glucose was measured after 10 min of incubated mixture at 37 celcius degrees. All tubes were evaluated for hemolysis, icterus, and lipemia. The CYANSMART device (ELITEK) was used to analyze the samples. Triglyceride and glucose reagents were kept at a temperature of 18-25°C for 15-20 minutes. After each test, a calibration and control procedure was performed.

**Figure 3.** Semi-automatic biochemistry analyzer CYANSmart

All samples were measured at the beginning and their values were considered control values

2.3 TyG index Glucose and triglyceride results from each participant were necessary to calculate the TyG index. The TyG index is calculated using the formula  $\ln [\text{triglyceride (mg/dL)} \times \text{fasting blood glucose (mg/dL)}/2]$  and is expressed on a logarithmic scale (Jeong et al., 2021)

#### 2.4 Statistical analysis

Before statistical analysis, participants were classified into 5 groups of smokers: only cigarette smokers, non-cigarette smokers, E-cigarette smokers, ex-cigarette smokers, and dual smokers (cigarette and E-cigarette smokers). Also participants were classified into the following insulin resistance groups according to the median TyG index (8.5): low insulin resistance group ( $< 8.5$ ) and high insulin resistance group ( $\geq 8.5$ ) (Jeong et al., 2021). IBM SPSS statistics version 21 was used to perform multinomial logistic regression and correlations between lifestyle habits and the TyG index. Two-sided  $p < 0.05$  was considered statistically significant.

#### Results of the study

**Table nr 1.** Indicates the statistical relationship between the Body Mass Index and the TyG index. According to statistical processing, we have a statistically significant relationship ( $P=0000$ ).

#### Paired Samples Test

#### 4. Discussions

Insulin resistance can be assessed by the Triglyceride-Glucose Index (TyG), a simple, low-cost and easy-to-apply method. With this index, the risk of patients developing pathologies can be calculated. cardiovascular disease, diabetes type II.

There are various studies that show the role of this index in predicting cardiovascular events with sensitivity and specificity values between 67 and 96% and 32.5-85%, respectively (Sánchez-García et al., 2020) as well as studies others that show the connection of TyG diabetes type II. (MAEDICA – a Journal of Clinical Medicine <https://doi.org/10.26574/maedica.2021.16.3.375> 2021; 16(3): 375-381)

Since the sedentary life is important for these pathologies, this study discussed the relationship between the TyG index and the sedentary life of students after the COVID-19 pandemic.

From our study, it was shown that there is a statistically significant relationship of sedentary factors (alcohol, physical activity, body weight, smoking) with TyG. These results are probably related to the lack of physical activity due to the isolation, perhaps due to the increased consumption of alcohol and cigarettes as an anti-anxiety tool to overcome the isolation, however, this should be verified in a wider group.

Also, it would be interesting if this study were carried out on the same group after a few years to see if people with high TyG would manifest Type II Diabetes, so TyG could be seen as an effective screening tool in predicting the control of diabetes. glycemia and insulin resistance in T2DM

#### 5. Acknowledgement

This study was conducted at the Biochemical Laboratory at Aldent University. A special thanks goes out to Jona Keri, and Iris Plaku, for their help, support and review.

#### Özet

Kanser, hücrelerin kontrolsüz bir şekilde artması ve büyümesiyle ilişkili en ölümcül olan hastalıklardan biridir. En yaygın kanser tipleri, meme, akciğer, mide, kolon, prostat ve cilt kanseridir. Ancak kanser her organda oluşabilir. Kanser evresine, türüne, hastanın sağlık durumuna göre farklı kanser tedavi yöntemleri vardır. Bunlar arasında radyoterapi, kemoterapi, cerrahi yöntemler, hipertermi, biyolojik tedaviler, fotodinamik tedavi, kök hücre nakli, lazer tedavisi, kan ürünlerinin bağışı, hormon tedavileri veya immünoterapi gibi yöntemler sayılabilir. Klasik kanser tedavilerinin ağır yan etkileri, tümörlü hücrelerin yanında sağlıklı hücrelerinde zarar görmesi gibi olumsuzluklar yüzünde farklı tedavi yöntemleri araştırılmaya devam etmektedir. Nanofiberlerin yüksek yüzey alanı, farklı polimer çeşitleri ile kompozit olarak farklı özelliklere sahip malzeme üretme olanağı gibi avantajları, bu malzemelerin kanser tedavisinde kullanılabilirliğinin araştırılmasını çekici kılmaktadır. Bu çalışma, manyetik duyarlı elektroğirilmiş nanofiberlerin ve çoklu uyaranlara duyarlı elektroğirilmiş nanofiberlerin kanser tedavisinde kullanımına ilişkin çalışmalarla ilgili perspektif sunmaktadır.

#### Usage of magnetic sensitive or multi-sensitive electrospun nanofibers for cancer treatment

#### Abstract

Cancer is one of the most fatal diseases associated with the uncontrolled increase and growth of cells. The most common types of cancer are breast, lung, stomach, colon, prostate and skin cancer. However, cancer can occur in any organ. There are different cancer treatment methods depending on the stage and type of cancer and the health condition of the patient. These include methods such as radiotherapy, chemotherapy and surgical methods, hyperthermia, biological treatments, photodynamic therapy, stem cell transplantation, laser treatment, donation of blood products, hormone treatments or immunotherapy. Different treatment methods continue to be investigated due to the negative effects of classical cancer treatments such as severe side effects and damage to healthy cells as well as tumor cells. Advantages of nanofibers, such as high surface area and the possibility of producing materials with different properties as composites with various polymer types, make it attractive to investigate the usability of these materials in cancer treatment. This study focuses on studies on the use of magnetically responsive electrospun nanofibers and multi-stimulus-sensitive electrospun nanofibers in cancer treatment.

**Keywords:** Cancer, nanofiber, cancer treatment, magnetic sensitive nanofiber, multi-sensitive nanofiber

## Kanser ve klasik tedavi yöntemleri

Kanser insan hastalıkları arasında kalp hastalıklarından sonra gelen en ölümcül hastalık olarak bilinmektedir. Yapılan çalışmalar önümüzdeki yıllarda kanser vakalarının artacağını göstermektedir. 2025 yılına kadar yılda 20 milyondan fazla kanser vakası olacağı tahmin ediliyor (Zugazagoitia ve ark, 2016). Kanser hücre büyümesini ve çoğalmasını kontrol eden mekanizmanın doğru çalışmamasından kaynaklanır. Klinik belirtileri ağrı, ülserler, sıklıkla şişlikler, kanama gibi durumlarla kendini gösterir. Sistemik belirtiler kilo kaybı, yorgunluk ve iştah kaybıdır. Kanser tedavisi üzerine tıp dünyası ve birçok çeşitli alandan araştırmacılar çalışmalar yapmaktadır (Wenhua ve ark, 2022). Kanser tedavileri genellikle radyoterapi, kemoterapi ve cerrahi yöntemler ile yapılırken, bazen hipertermi, biyolojik tedaviler, fotodinamik tedavi, kök hücre nakli, lazer tedavisi, kan ürünlerinin bağıışı veya hormon tedavileri gibi yöntemler de kullanılabilir. Klasik kanser ilaçları kanser hücrelerinin DNA replikasyonunu engelleyerek etki gösterir, ancak araştırmalar seçici bir etki yaratmadığını göstermektedir. Bu tedavilerin yan etkileri arasında ağız yaraları, yorgunluk, ağrı ve enfeksiyonlar, saç dökülmesi, mide bulantısı bulunabilir. Alternatif tedavi yöntemleri araştırılmaktadır, ancak kanserin karmaşıklığı ve farklı türlerinin varyasyonları, tümör hücrelerinin yanında sağlıklı hücrelerde zarar vermeden etkili bir tedavi bulmayı zorlaştırmaktadır (Han ve Li, 2011; Maeng ve ark, 2010; American Cancer Society, 2023).

## Elektroğrılmış (elektrospun) nanofiberler

Elektroğirme yöntemi nanofiber üretim yöntemleri arasında en sık kullanılan yöntemlerden biridir. Temel fizik, elektrik fiziği, polimer kimyası, akışkanlar dinamiği gibi birçok alanı içinde barındıran multidisipliner bir yöntemdir. Elektroğirme cihazı yüksek voltaj güç kaynağı, besleme ünitesi (metal iğne, şırınga v.b.), Toplayıcı (iletken plaka, döner silindir v.b.) olmak üzere üç ana kısımdan oluşur. Yöntemin temel prensibi; polimer eriğinin besleme ünitesine alındıktan sonra güç kaynağı yardımı ile uygulanan voltaj sayesinde ilk önce damlacık halini alması ardından manyetik alan içinde çekilerek incilmesi ve lif yapısını alması şeklinde tanımlanabilir (Li ve ark, 2004; Xue ve ark, 2019).

Elektroğirme yöntemiyle nanofiber üretiminde kullanılabilen polimer çeşidinin çok fazla olması istenilen özelliklere sahip nanofiber üretimini mümkün kılmaktadır. Elektroğrılmış (elektrospun) nanofiberler bu sebepten birçok farklı uygulama alanında kullanılmaktadırlar ancak bu yazıda konuyla bağlantılı olarak biyomedikal uygulamalardaki kullanımına yer verilecektir. Elektroğrılmış nanofiberler yüksek çözünürlük, yüksek yüzey-hacim oranı ve sağladığı geniş kullanım alanı gibi çeşitli avantajlara bağlı olarak özellikle farmasötik alanda ve biyomedikal uygulamalarda geniş kullanım alanı bulmaktadır. Nanofiber teknolojisi, yanık ve yara bakımı, organ onarımı, osteoporoz, doku rejenerasyonu ve ilaç dağıtımı gibi biyomedikal alanda yaşanan zorluklara potansiyel bir çözüm olarak birçok araştırmacının dikkatini çeken heyecan verici bir alandır. Güncel çalışmalar göstermiştir ki, biyomedikal nanoliflerin sağladığı geniş yüzey alanı, gelişmiş hücre aktiviteleri, ilaç kapsüllenmesi ve ilaç salınım hızının kontrolü için kullanılabilir. Malzeme seçimleri ve lif oryantasyonunun ayarlanmasıyla elektroğirme prosesi optimize edildiğinde, hücre farklılaşması ve ilaç salınım kontrolü gibi alanlarda daha fazla gelişme sağlanabilir olması, araştırmacıların ilgisini giderek daha çok çekmektedir (Leung ve Ko, 2011; Yıldız ve ark, 2020; Kanmaz ve ark, 2018).

## Manyetik duyarlı elektroğrılmış nanoliflerin kanser tedavisinde kullanımı

Kanser tedavi yöntemleri arasında en sık kullanılan kemoterapi ve radyoterapi olmasına rağmen sağlıklı dokularada zarar veren, toksisite ve olumsuz yan etkileri olan yöntemlerdir (Mokhosi ve ark, 2022). Lokal tümör bölgede tedavinin yoğunlaşması ve komşu sağlıklı hücrelerin en az düzeyde hasar görmesi hedefiyle manyetik elektroğrılmış nanoliflerin kanser tedavisi için kullanımı dikkatleri üstüne çekmektedir. Bu malzemeleri elektroğirme yönteminde kullanılabilen birçok polimer ile manyetik nanoparçacıkları kompozit oluşturarak hazırlamak mümkündür (Huang ve ark, 2012). Böylece manyetik özellik kazanan nanolifler dış manyetik alan etkisiyle taşınabilir olması onları hedef bölgeye duyarlı kontrollü ilaç salınımı için mükemmel taşıyıcılar yapmaktadır. **Şekil 1**' de gösterildiği üzere klasik ilaç dağıtımı hasarlı hücre bölgesinin yanı sıra sağlıklı hücreleride etkilemektedir. Manyetik ilaç yüklü nanolifler dış manyetik alan etkisi ile manipüle edilip hedef bölgeye çekilebilir (Patel ve Gundloori, 2023; Contreras-Cáceres ve ark, 2019).

Şekil 1. Manyetik özellikli ve klasik elektroerilmiş nanoliflerin ilaç salım farkı

Wang ve arkadaşları  $Fe_3O_4$  manyetik parçacıklarını iki farklı selüloz türevi polimerle kompozit halinde elektroerime yöntemi kullanarak üretmişlerdir. Üretilen manyetik nanolifler hedefe duyarlı ilaç salım sisteminde kullanılmış, model ilaç olarak indometasin (IDN) ve aspirin seçilmiştir. Özellikle sindirim sisteminde hedef bölgeye duyarlı ilaç salımı için olumlu sonuçlar alınmıştır (Wang ve ark, 2012). Başka bir çalışmada doksorubisin hidroklorür (DOX) yüklü elektroerilmiş kitosan/kobalt ferrit/titanyum oksit nano lifleri sentezlenmiştir. Bölgesel ilaç salım incelemesi ardından nanoliflerinin lokalize kanser tedavisinde kullanılabileceği sonucuna varılmıştır. (Radmansouri ve ark, 2018).

Manyetik nanolifler lokal bölge ilaç salım uygulamalarının yanı sıra hipertermi kanser tedavilerinde sağladığı pozitif etkiler nedeniyle dikkat çekmektedir. Hipertermi klasik kemoterapi ve radyoterapi yöntemi gibi etkili olan bir kanser tedavi yöntemidir (Hadi ve ark, 2019; Wei ve ark, 2022). Tümör hücreleri sağlıklı hücelere göre  $41^\circ$  ila  $45^\circ C$  arasındaki yüksek sıcaklıklara daha duyarlıdır. Bu tedavi yönteminde sağlıklı hücelere mümkün olduğu kadar korunarak tümör hücrelerin ısıtılarak apoptoza uğraması sağlanır (Moroz ve ark, 2002). Hipertermi etkisi yaratmak için manyetik nanopartiküller (MNP) dış bir manyetik alana maruz kaldığında manyetik enerji termal enerjiye dönüştürülebilir, busayede tümör dokusuna nüfuz etmiş olan MNP hücrelerin ölümü için gereken ısıyı sağlamış olur (Hervault ve Kim Thanh, 2014; Schneider-Futschik ve Reyes-Ortega, 2021; Mamun ve Sabantina, 2023).

Polikaprolakton (PCL)/ $Fe_3O_4$  kompoziti portatif bir elektro erime cihazı ile sentezlenmiş ısıtma verimi sonuçlarına göre hipertermi tevasi için kullanılabileceği öne sürülmüştür (Hu ve ark, 2020). Song ve arkadaşları Elektroerime yöntemiyle  $Fe_2O_3$ /Poliüretan manyetik nanolifleri sentezlemiş, manyetik nanolifler dış manyetik alan etkisiyle 70 saniyede  $43^\circ C$  sıcaklığa ulaşmıştır (Song ve ark, 2018). Yine elektroerime yöntemiyle yağ asidi (Laurik asid) içine MNP kapsüllenmiş hipertermi tevasi için kullanılabilirliği araştırılmıştır. MNP  $40-48^\circ C$ 'de  $70-75 Jg^{-1}$  ısı emme ve salma kapasitelerine sahip olduğu bildirilmiştir (Sarier ve ark, 2018). Wei ve ark. önemli bir cilt kanser türü olan melenomun lokalize termo-kemoterapi tedavisi için ısıya duyarlı (açık-kapalı) ilaç yüklü manyetik nano elyaflar önerdi. Doğal antikanser ajanı olan kurkimin yüklü manyetik nano elyafların dış manyetik alan etkisiyle ısısının arttırıp kurkimin salımının kontrol edilebildiği gösterildi (Wei ve ark, 2022). Huang ve ark. polistiren/demir oksit nanoparçacıklarını elektroerime yöntemiyle sentezledi. Yüksek ısıtma kapasitesine sahip MNP lere bağlı olan kanser hücrelerinin manyetik alan etkisi altında ısınmaya bağlı olarak öldüğü gösterildi (Huang ve ark, 2012). 2021 yılında yapılan bir çalışmada poliakrilonitril/ $Fe_3O_4$  manyetik özeliğe sahip nanoliflerin manyetik alan altında ısıtma ve hareket kabiliyetleri test edildi. Manyetik nanolifler  $15.57 kA/m$ 'lik bir manyetik alanda  $49.9^\circ C$ 'ye kadar ısı üretti ve  $2,15 mm/sn$ 'lik bir hareket hızı sağladı (Lee ve Kim, 2021). Matos ve ark. manyetik hipertermi uygulamaları için selüloz asetat ve  $Fe_3O_4$  MNP' leri birleştirip kompozit membranlar üretti. Manyetik özellikli membranlar iyi ısıtma değerleri gösterdi. Hipertermi tedavisinde komşu sağlıklı hücrelerin zarar görmemesi için ısıtma değerlerinin nanopartikül konsantrasyonunun değiştirilerek düzenlenebileceği belirtildi (Matos ve ark, 2018). 2013 yılında yapılan bir çalışmada  $Fe_2O_3$ /Poliüretan nanoliflerin yüksek frekans manyetik alan altında ısıtma değerleri incelendi. Yüksek frekanslı manyetik alan altındaki kompozit nanolifler  $Fe_2O_3$  miktarına ve manyetik alan kuvvetine bağlı olarak saf poliüretan nanoliflere göre %3-17'lik bir sıcaklık artışı göstermiştir (Park ve ark, 2013).

## Çoklu uyarılara duyarlı elektroğrılmış nanoliflerin kanser tedavisinde kullanımı

Uyarılara yanıt veren akıllı nanoliflerin kanser tedavilerinde kullanımında, birden çok uyarana yanıt veren malzemeler geliştirilerek sinerjistik olarak nanoliflerin faaliyetini artırma yönünde çalışmalar yapılmaktadır. Elektroğirme yönteminde kullanılabilir olan polimer çeşitliğinin çok fazla olması bu anlayışı desteklemektedir. Akıllı ilaç tasarımlarında seçilen polimer dış ortamdan gelen çeşitli uyarılara karşı şişerek ya da büzülerek cevap verebilmektedir. Bu kompozitlere MNP de dahil olunca ışık, sıcaklık, Manyetik alan, pH gibi manipülasyona neden olan özellikler aynı malzeme içinde birlikte kullanılabilir (Zhao ve Cui 2020; Li ve ark, 2022; Kim ve ark, 2013; Samadzadeh ve ark, 2021). **Şekil 2.**' de kanser tedavisinde kullanılan nanoliflerin uygulamaları verilmiştir.

### Şekil 2. Elektro eğrilmiş nanoliflerin kanser tedavisi uygulamaları

Melanom kanseri apoptozunu uyarmak için Kim ve ark. dış bir manyetik alandan yararlanarak eş zamanlı olarak ısı üreten ve buna bağlı olarak ilaç salımı gerçekleştiren bir malzeme tasarlamışlardır. Elektroğirme yöntemiyle sentezlenen malzeme, sıcaklığa duyarlı bir polimer, manyetik partiküller ve bir antikanser ilacı (doksorubisin) içermektedir. Manyetik alan etkisiyle kendi kendine ısı üreten MNP' ler sayesinde sıcaklığa duyarlı polimer şişmekte ve ilaç salımı gerçekleşmektedir. Rapora göre insan melanom hücrelerinin %70'i ısı ve ilacın çifte etkisiyle 5 dakika içinde ölmüştür (Kim ve ark, 2013). Başka bir çalışmada hipertermi ve kemoterapinin birlikte uygulaması için dış bir manyetik alan yardımıyla kanser bölgesinde hem pH' a bağlı ilaç salımı hemde ısı ile kanser hücrelerini öldürcek bir yöntem önerilmiştir. Elektroğirme yoluyla sentezlenen katekolik manyetik nanoliflere antikanser ilacı Bortezomib (BTZ) bağlandı. Nanoliflerin katekol kısımları ile BTZ'nin borat kısımları pH değişimleri ile bağlanma ve salınma gerçekleştirdi. Bununla birlikte hipertermi tedavileri için demir oksit nanopartiküller kullanıldı. Yapılan in vitro çalışmalar, katekolik manyetik nanoliflerin mükemmel bir antikanser etkisi sergilediğini göstermiştir (GhavamiNejad ve ark, 2015). Bortezomib (BTZ) antikanser ilacının kullanıldığı başka bir çalışmada elektroğirme yöntemiyle sentezlenen ilaç yüklü manyetik nanoliflerin, manyetik alan ile hem hipertermi uygulaması hem de sinerjistik kanser tedavisini mümkün kılmak için kanser hücresine özgü ilaç salımında kullanılabilir olduğu bildirildi (Sasikala ve ark, 2016). Başka bir hipertermi uygulamasıyla birlikte kontrollü ve sürekli ilaç salım uygulamasında denemek üzere; Akıllı nanolifli yapı iskeleleri, demir oksit (II, III) manyetik nanoparçacıklar, metformin ve gözenekli silika nanoparçacıklar ile kompozit oluşturulmuş, sıcaklığa duyarlı bir kopolimerin elektroğrılmasıyla üretilmiştir. Sentezlenen ilaç yüklü manyetik nanoliflerin, cilt kanseri tedavileri için ısı ve ilaç salımının birlikte sinerjistik etkisi olduğu bildirilmiştir (Samadzadeh ve ark, 2021). Meme kanseri tedavisinde kullanılan Doksorubisinin elektroğirme tekniği ile sentezlenen membranlarda pH ve redoks uyarılarına göre salım profilleri incelendi. Elektroğrılmış membran asidik ve indirgeyici ortamda uyarılan ikili kontrollü salım göstermiş, meme kanseri hücre dizilerinde ciddi sitotoksik etki yaratmıştır (Federico ve ark, 2022).

### Sonuç ve gelecek perspektifler

Nanoteknoloji, klinik bilimlere destek olan nanofiberlerle kontrollü ilaç salımı gibi konularda umut verici bir yaklaşım sunmaktadır. Nanofiberlerin, sürekli ilaç salımı göstererek ve hedef bölgeye yönlendirilebilir şekilde tasarlanabilmeleri sayesinde kanser hücrelerine karşı daha iyi performans göstermesi bu alandaki çalışmaların daha çok artmasını sağlayacaktır. İlaç ve polimer seçimi, sürekli ilaç salımı için doğru kombinasyonun belirlenmesi açısından önemlidir. Manyetik özellikte nanolifler üretilebilmesi, çeşitli uyarılara tepki veren polimer seçme imkanı, bu alandaki çalışma pergelene oldukça genişletmektedir. Nanofiberler, antikanser ilaçlarını ve doğal özleri kapsülleyebilir. Manyetik

duyarlı nanofiberler ya da çoklu uyaranlara duyarlı nanofiberler tek tip ilaç yüklü nanofiberlere göre tercih edilebilir ve daha etkili bir kanser tedavisi sağlayabilir. Ancak, ilaç salımının hedeflenen şekilde sağlanması ve metastatik kanser hücrelerinin tedavisi için daha fazla çalışma gerekmektedir. Bu nedenle, bu nanofiberlerin ticarileştirilmesi için daha fazla araştırma yapılmalıdır.

## ORAL PRESENTATION

### Comparison of propofol alone and different doses of ketofol combinations on systolic, diastolic, and mean arterial pressures in dogs

#### Abstract

This study aimed to compare the effects of propofol, either alone or in combination with varying doses of ketamine, on systolic, diastolic, and mean arterial blood pressure in unpremedicated dogs. Twenty-eight crossbred dogs were randomly divided into four groups: a Propofol-only group and three Ketofol groups with ketamine ratios of 1:1, 1:2, and 1:3, administered intravenously at a constant rate of 0.6 mg/kg/minute. Noninvasive blood pressure measurements were taken every five minutes for 60 minutes. The results indicated that the Propofol group showed no significant change in systolic pressure over time ( $p > 0.05$ ). However, diastolic and mean arterial pressures decreased at various intervals. In contrast, the Ketofol 1:1 combination led to a consistent increase in systolic, diastolic, and mean arterial blood pressure over time ( $p < 0.05$ ). The Ketofol 1:2 combination did not significantly affect systolic and mean blood pressure ( $p > 0.05$ ) but increased diastolic pressure at various intervals. The Ketofol 1:3 combination did not significantly alter systolic and mean blood pressures but raised diastolic pressure; however, it proved inadequate in achieving an optimal plane of anesthesia, leading to the appearance of withdrawal reflex. Blood pressure changes were related to the varying ketamine amounts in the mixture. In conclusion, propofol reduced diastolic and mean arterial pressure, whereas its combination with ketamine resulted in a significant increase in systolic, diastolic, and mean arterial pressure in unpremedicated healthy dogs. Among the Ketofol combinations, the 1:2 ratio provided the closest approximation to initial blood pressure levels when compared to the 1:1 and 1:3 combinations. The Ketofol 1:3 combination could be misleading for blood pressure determination due to its inadequacy for achieving optimal anesthesia. The addition of ketamine to the propofol mixture can help balance blood pressure during propofol anesthesia.

**Keywords:** anesthesia, blood pressure, dogs, ketamine, ketofol, propofol.

#### INTRODUCTION

Anesthesia can influence blood vessel tone, potentially leading to fluctuations in blood pressure. Effective blood pressure management is crucial for maintaining the proper functioning of these organs. Anesthesia can induce a drop in blood pressure, a condition referred to as hypotension. Hypotension can diminish the blood flow to vital organs, possibly resulting in organ dysfunction or damage. Conversely, excessively high blood pressure, referred to as hypertension, during anesthesia can be problematic as well. It heightens the risk of bleeding, blood vessel damage, and other complications. (Den Boer et al. 1993; Akata 2007; Shi and Rodríguez-Contreras 2022)

Inadequate management of blood pressure during anesthesia in dogs can lead to a variety of complications, including cardiovascular issues, organ dysfunction, and an elevated risk of adverse events during surgery. During surgery, blood pressure serves as one of the continuously monitored vital signs. Surgery can elevate the body's demand for oxygen and nutrients due to factors such as pain, surgical trauma, and changes in body position. It acts as an indicator of the patient's response to anesthesia. Sudden shifts in blood pressure can signal potential issues such as anesthetic overdose, inadequate anesthesia, or other complications, enabling anesthesiologist to make timely adjustments. (Mazzaferro and Wagner 2001; Hughes 2008)

Different anesthesia drugs and techniques can impact blood pressure differently. Propofol, a common intravenous anesthetic in dogs, can cause a temporary drop in blood pressure due to its vasodilatory effect. Ketamine, often used in canine anesthesia, stimulates the sympathetic nervous system, generally increasing blood pressure. Ketamine is commonly used in combination with other agents for balanced anesthesia. When ketamine and propofol are combined for anesthesia in dogs, their effects on blood pressure are influenced by various factors, including dosage, rate of administration, individual patient characteristics, and the presence of other medications. (Haskins et al. 1986; Cullen 1996; Hughes 2008)

The objective of this study was to test the following null hypothesis: The administration of propofol alone or ketamine-propofol ratios at 1:1, 1:2, and 1:3 will not result in a change in systolic, diastolic and mean arterial pressure in unmedicated dogs.

## **MATERIALS AND METHODS**

The study was approved by the Atatürk University Ethics Committee for Animal Experiments (Approval No. 2015/6/119) and conducted at the Atatürk University Veterinary Teaching Hospital with privately owned male dogs brought in for castration surgery. The owners of the dogs provided written informed consent for their participation.

The animals were housed individually, and they were fasted for a minimum of 12 hours prior to anesthesia, whereas their water consumption was not restricted.

### **Animals**

Twenty-eight male dogs of mixed breeds were enrolled in the investigation. The inclusion criteria included canines aged 1 to 6 years without a history of systemic disease and a clean clinical examination, complete blood profile, and serum chemistry analysis. The physical status score of the canines according to the American Society of Anesthesiologists was I, and the body condition score was 4 or 5 out of 9.

### **Drugs**

Propofol (20 mg/mL, Fresenius Kabi, Graz, Austria) and ketamine (100 mg/mL, Ketazol, Interhas, Richter Pharma AG, Wels, Austria) were used in the current study. This mixture was manufactured daily to ensure that it was sterile and aseptic. Before administration, the admixture was combined into a single infusion container for each subject. Three distinct propofol and ketamine combinations were used for constant rate infusion (CRI): Ketofol 1:1, Ketofol 1:2, and Ketofol 1:3. The Ketofol 1:1 mixture contained 10 ml (1000 mg) of ketamine and 50 ml (1000 mg) of propofol, whereas the Ketofol 1:2 mixture contained 10 ml (1000 mg) of ketamine and 100 ml (2000 mg) of propofol. The Ketofol 1:3 mixture included 10 ml (1000 mg) of ketamine and 150 ml (3000 mg) of propofol.

### **Study design**

The research was a longitudinal experimental clinical trial. Using a random drawing, dogs were assigned to anesthesia treatment groups.

The dogs were divided into four groups, each containing seven animals, and designated as group P, group Ketofol 1:1, group Ketofol 1:2, and group Ketofol 1:3. Each group received the assigned treatment for both induction and maintenance of anesthesia, with no pre-anesthetic medications being administered. The loading dose for induction of anesthesia was injected into the previously catheterized right cephalic vein at a rate of one milliliter every 15 seconds until jaw relaxation was observed, after which the dog was sternally positioned and intubated. Dogs breathed room air spontaneously.

Utilizing a volumetric infusion device (Birset IV Master, Birtan Medical, Ankara, Turkey), anesthesia was administered. Before the procedure, the IV infusion hose set was verified on the volumetric pump, and the same brand of IV set was used throughout the entire study. (Senocak et al. 2021) The total volume of substance in each group's mixture was administered as a CRI at a rate of 0.6 mg/kg/minute for sixty minutes. During the anesthesia, the pedal reflex was continuously evaluated by compressing the hindlimb pulvinus at one-minute intervals to determine depth of anesthesia.

### **Patient monitoring**

Vital sign data was collected utilizing the Veterinary Patient Monitor (MVM Medical, GT9000F, Istanbul, Turkey) to track the animal's vital signs. To ascertain the systolic arterial pressure, diastolic arterial pressure,

and mean arterial pressure, a blood pressure cuff with a circumference equivalent to 40% of the right pelvic limb circumference was placed proximal to the tarsus. (Şenocak 2023)

To obtain the respiratory frequency, and heart rate, electrocardiographic leads were attached to the extremities. A rectal probe was inserted into the rectum in order to measure rectal temperature. The end-tidal carbon dioxide tension adapter was also attached to the endotracheal tube connector for capnography. Manual ventilation was provided using an ambu bag when the patient's saturation level fell below 92%.

The systolic, diastolic, and mean arterial pressure data were recorded at prior to the study as baseline (BL), following intubation (T0), and every five minutes up to 60 minutes. When the swallowing reflex was observed, the dog was positioned on its left side and extubated after the final measurement at T60.

The surgical stimulus due to the open orchietomy was started at T10 after induction of anesthesia.

### Statistical analysis

The data's normality was assessed with the Shapiro-Wilk test, and variance homogeneity was checked using the Levene test. To assess the overall significance of treatment differences, a mixed ANOVA was conducted, as indicated by the omnibus p-value. For comparisons between the BL and subsequent time points (with time as the dependent variable), a repeated measures one-way ANOVA was performed, followed by post-hoc correction using the LSD method. In cases where Mauchly's Test of Sphericity was inconclusive, the degrees of freedom were adjusted using a Greenhouse-Geisser correction.

Blood pressure data from different groups underwent Univariate ANOVA for analysis, and the Post-Hoc LSD multiple comparison test was applied to assess pairwise differences.

In the study, parametric data were represented as mean values with standard deviations. The differences in means between different treatments were displayed as mean differences along with their corresponding 95% confidence intervals, showing the range from the lower to the upper bound of the CI.

We established a significance alpha level of 0.05. The statistical analyses were carried out using SPSS software, specifically Version 22.

### RESULTS

In the investigation, a total of twenty-eight healthy dogs were included. Nonetheless, one animal from Group Ketofol 1:1 was excluded from the investigation due to apneic episodes. The animal recovered from anesthesia without any complications after receiving oxygen support via a positive-pressure ventilator. The study was conducted with six dogs in this group. During the investigation hypotension (mean arterial blood pressure < 60 mmHg) was not observed.

The dogs included in the study had an average age of  $2.9 \pm 1.1$  years, and their average weight was  $17.6 \pm 6.4$  kg.

Throughout the maintenance of anesthesia, two dogs in the Ketofol 1:3 treatment group exhibited a slight pedal reflex due to the light plane of anesthesia.

Propofol group had no significant change in systolic pressure compared to BL over time ( $p > 0.05$ ). However, it was observed that diastolic pressure was decreased at T10 with a mean difference of 23.14 mmHg (95% CI 7.59-38.69,  $p=0.011$ ), T15 with a mean difference of 26.29 mmHg (95% CI 9.56-43,  $p=0.008$ ), T20 with a mean difference of 24.43 mmHg (95% CI 7-41.85,  $p=0.014$ ), T25 with a mean difference of 19 mmHg (95% CI 4.25-33.75,  $p=0.02$ ), and T30 with a mean difference of 19 mmHg (95% CI 4.55-33.45,  $p=0.018$ ) compared to the BL. In addition, mean arterial pressure was decreased at T5 with a mean difference of 20 mmHg (95% CI 9.73-30.27,  $p=0.003$ ), T10 with a mean difference of 16.7 mmHg (95% CI 2.48-30.95,  $p=0.028$ ), T15 with a mean difference of 19.43 mmHg (95% CI 3.84-35,  $p=0.022$ ), T20 with a mean difference of 18.29 mmHg (95% CI 1.28-35.29,  $p=0.039$ ), T30 with a mean difference of 12.57 mmHg (95% CI 0.7-24.44,  $p=0.041$ ) compared to the BL.

Ketofol 1:1 combination increased systolic blood pressure at T55 with a mean difference of 10 mmHg (95% CI 3.17-16.8,  $p=0.013$ ), diastolic blood pressure at T50 with a mean difference of 21.83 mmHg (1.47-42.2,  $p=0.04$ ), and mean arterial pressure at T25 with a mean difference of 19.83 mmHg (95% CI 2.8-36.8,  $p=0.03$ ), T30 with a mean difference of 20.3 (95% CI 3.2-37.4,  $p=0.028$ ), T35 with a mean difference of 23 mmHg (95% CI 2.68-43.3,  $p=0.033$ ), T40 with a mean difference of 24.33 mmHg (95% CI 3.36-45.31,  $p=0.031$ ), T45 with a mean difference of 21.5 mmHg (95% CI 2.33-40.67,  $p=0.034$ ), T50 with a mean difference of 24 mmHg

(95% CI 5.76-42.28,  $p=0.02$ ), T55 with a mean difference of 24 mmHg (95% CI 5.2-42.8,  $p=0.022$ ), T60 with a mean difference of 22.5 mmHg (95% CI 2.8-42.16,  $p=0.032$ ) compared to BL.

Ketofol 1:2 combination was not changed systolic and means blood pressure significantly ( $p > 0.05$ ). However, it was increased diastolic pressure at T45 with a mean difference of 15.43 mmHg (95% CI 4.1-26.79,  $p=0.016$ ), T50 with a mean difference of 16.57 mmHg (95% CI 5.77-27.34,  $p=0.009$ ), T55 with a mean difference of 15.14 mmHg (95% CI 5.28-25.1,  $p=0.009$ ), and T60 with a mean difference of 23.29 mmHg (95% CI 4.39-42.18,  $p=0.024$ ) compared to the BL.

Ketofol 1:3 combination was not changed systolic and mean blood pressures significantly ( $p > 0.05$ ) However, it was increased diastolic blood pressure T5 with a mean difference of 21.43 mmHg (95% CI 2.8-40.1,  $p=0.031$ ), T10 with a mean difference of 24.57 mmHg (95% CI 4.9-44.2,  $p=0.022$ ), T15 with a mean difference of 24.43 mmHg (95% CI 4.72-44.13,  $p=0.023$ ), T20 with a mean difference of 27.43 mmHg (95% CI 4.15-50.7,  $p=0.028$ ), T30 with a mean difference of 33.57 mmHg (95% CI 12.44-54.7,  $p=0.008$ ), T35 with a mean difference of 33.43 mmHg (95% CI 13.2-53.67,  $p=0.007$ ), T40 with a mean difference of 32.43 mmHg (95% CI 12.03-52.82,  $p=0.008$ ), T45 with a mean difference of 33.86 mmHg (95% CI 15.84-51.87,  $p=0.004$ ), T50 with a mean difference of 32.57 mmHg (95% CI 12.53-52.61,  $p=0.007$ ), T55 with a mean difference of 32.57 mmHg (95% CI 11.89-53.25,  $p=0.008$ ), and T60 with a mean difference of 33 mmHg (95% CI 10.66-55.34,  $p=0.011$ ) compared to the BL.

In overall consideration, systolic blood pressure was significantly higher in Ketofol 1:3 group ( $146.15 \pm 7.91$  mmHg), Ketofol 1:1 ( $144.37 \pm 5.57$  mmHg), and Ketofol 1:2 ( $142.61 \pm 7.24$  mmHg) compared to Propofol group ( $136.59 \pm 13.24$  mmHg), ( $p < 0.01$ ). In addition, systolic blood pressure was significantly ( $p < 0.01$ ) higher in Ketofol 1:1 group compared to the Ketofol 1:3. It was also significantly ( $p=0.007$ ) higher in Ketofol 1:3 group compared to Ketofol 1:2 group.

Diastolic blood pressure was significantly higher in Ketofol 1:3 group ( $110.34 \pm 13.68$  mmHg), Ketofol 1:1 ( $106.41 \pm 18.14$  mmHg), and Ketofol 1:2 ( $103.49 \pm 20.37$  mmHg) compared to the Propofol group ( $95.77 \pm 23.51$  mmHg), ( $p < 0.05$ ). In addition, diastolic pressure was significantly higher in Ketofol 1:3 group compared to the Ketofol 1:2 ( $p < 0.01$ ).

Mean arterial blood pressure was significantly higher in Ketofol 1:3 ( $125.93 \pm 12.23$  mmHg), Ketofol 1:1 ( $125.91 \pm 11.93$  mmHg), and Ketofol 1:2 ( $121.96 \pm 15.79$  mmHg) compared to the Propofol group ( $113.01 \pm 21.44$  mmHg), ( $p < 0.01$ ).

## DISCUSSION

This study has provided an evidence that propofol administration is associated with a reduction in both diastolic and mean arterial pressure. Conversely, when propofol is administered in combination with ketamine, a significant improvement is observed in systolic, diastolic, and mean arterial pressure among unpremedicated, healthy dogs. It is noteworthy that variations in the ratios of propofol and ketamine in the mixture can lead to diverse magnitudes of blood pressure fluctuations. Specifically, the utilization of Ketofol at a 1:3 ratio may be insufficient for achieving the requisite level of anesthesia, potentially resulting in the acquisition of erroneous blood pressure data. The incorporation of ketamine into the admixture exerts a discernible influence on the elevation of blood pressure, and the administration of Ketofol at a 1:2 ratio appears to offer the most precise approximation to the baseline blood pressure values.

Multiple techniques exist for assessing arterial blood pressure in dogs, including invasive approaches like direct arterial puncture, as well as noninvasive methods such as oscillometry and Doppler ultrasonography, typically employed in clinical settings. It is noteworthy that both invasive and noninvasive means of measuring systolic, diastolic, and mean arterial pressure have demonstrated comparable results (Stepien and Rapoport 1999) In the current investigation, we opted for a noninvasive approach to blood pressure measurement utilizing oscillometry. This method involved the use of a blood pressure cuff with a width equivalent to 40% of the circumference of the right pelvic limb. The cuff was positioned proximal to the tarsus to facilitate the noninvasive assessment of blood pressure.

Certain premedications, particularly alpha2 agonists, can exhibit an initial surge in arterial pressure, succeeded by a more protracted but mild decrease in blood pressure. (Vainio 1989) This phenomenon associated with premedication has the potential to obscure the primary drug's primary impact on blood pressure. In the current research, we deliberately abstained from using any premedication agents to isolate and elucidate the inherent effects of the primary drugs on blood pressure. We selected propofol and ketamine for induction of anesthesia

without the use of premedication. This combination is widely employed in anesthesia practices as a common choice. (Dogan et al. 2016; Yanmaz et al. 2020)

Blood pressure monitoring during the course of anesthesia serves as a valuable indicator of the anesthesia depth and provides insights into the potential presence of pain. (Saccò et al. 2013) Particularly, when confronted with surgical stimuli, deviations of 20% or more in blood pressure are conventionally regarded as indicative of a light plane of anesthesia or the potential existence of pain. (Şenocak 2023) In the context of our current investigation, it was observed that various combinations of propofol and ketamine at differing ratios elicited distinct alterations in systolic, diastolic, and mean arterial pressure. This variability may be attributed to the varying levels of ketamine within the administered mixtures (Smischney et al. 2012; Ghadami Yazdi et al. 2013)

Elevations in blood pressure can be attributed to various factors, including the white coat effect, anxiety, alertness, defensive responses, and the experience of pain. (Popilskis et al. 1993; Soares et al. 2012). Specifically, during surgical procedures, an increase in blood pressure is indicative of the dog perceiving a painful stimulus. Consequently, the monitoring of systolic blood pressure throughout surgery serves as a critical parameter for assessing the depth of anesthesia (Popilskis et al. 1993). However, it remains unclear whether the rise in blood pressure is primarily associated with the painful stimuli or is influenced by the pharmacological effects of administered drugs. In our study, surgical stimuli were introduced at the T10 level. Although systolic blood pressure did not exhibit significant changes, it did show a suspicious decrease. Notably, diastolic pressure and mean arterial pressure experienced a decrease within the initial thirty minutes, even at the T5 level of surgery. This observation suggests that this decrease may be attributed to both the chemical and physiological effects of propofol or the profound depression of the central nervous system when compared to the combination of propofol with ketamine. Alternatively, it could be related to the sympathomimetic effects of ketamine, stemming from increased monoamine release and the inhibition of presynaptic catecholamine reuptake. (Tso et al. 2004)

While propofol typically leads to a reduction in blood pressure, its combination with ketamine has been found to result in an elevation of blood pressure. This increase in blood pressure, particularly notable when using a 1:1 ratio of ketofol (ketamine combined with propofol), primarily manifested after the 25th minute and was particularly prominent in mean arterial pressure. The observation of withdrawal reflex in the group receiving propofol combined with ketamine at a 1:3 ratio led to the inference that this particular combination may not be adequate for achieving a sufficiently deep state of anesthesia. Consequently, the rise in blood pressure within this group could be attributed to the presence of consciousness. In contrast, when propofol was combined with ketamine at a 1:2 ratio, blood pressure remained relatively stable. Therefore, this particular combination warrants broader consideration and evaluation for its potential efficacy.

## CONCLUSION

In conclusion, this study has provided the hemodynamic effects of propofol and its combination with ketamine in unpremedicated healthy dogs. Propofol alone is associated with a reduction in both diastolic and mean arterial pressure, whereas the combination with ketamine results in a significant increase in systolic, diastolic, and mean arterial pressure. Importantly, the observed alterations in blood pressure are contingent upon the specific ratios of propofol and ketamine administered. Notably, the use of Ketofol at a 1:3 ratio may prove insufficient for achieving adequate anesthesia, potentially leading to erroneous blood pressure measurements could be attributed to the presence of consciousness. Conversely, employing Ketofol at a 1:2 ratio appears to provide the closest approximation to the baseline blood pressure levels. These findings underscore the critical role of drug ratios in managing anesthesia and monitoring hemodynamic stability in dogs.

#### Özet

İnsan beslenmesinin vazgeçilmez bir parçası olan ve günlük olarak sıklıkla tüketilen yoğurdun zengin besin içeriği ve insan sağlığına faydaları ile öne çıkan *Spirulina platensis* ile zenginleştirilmesiyle elde edilen fonksiyonel ürünün duyuşal niteliklerinin belirlendiği bu araştırmada, 4 farklı oranda (%0, %0,3, %0,6, %0,9) *Spirulina platensis* içeren 4 klasik ve 4 probiyotik olmak üzere 8 çeşit yoğurt üretilmiştir. Üretilen yoğurtların duyuşal nitelikleri 4 °C'de 1, 7, 14, 21 ve 28. günlerde analiz edilmiştir. Yoğurt üretiminde kullanılan *Spirulina platensis* tozunun, yoğurt örneklerinin duyuşal özellikleri üzerine olan etkisi önemli bulunmuştur. Yapılan duyuşal analizler sonucunda, yoğurt örneklerinin tümü duyuşal değerlendirmeler açısından 5 puan üzerinden 4-5 arasında puanlara sahip olmuşlardır. Tüm duyuşal değerlendirmeler gözönünde bulundurulduğunda; %0,3 oranında *Spirulina platensis* ihtiva eden (P%0,3), *Lactobacillus acidophilus*'lu, besin değeri yüksek yeni bir fonksiyonel yoğurt üretilebileceği kanıtlanmıştır. Ayrıca panelist değerlendirmelerine göre, %0,9 *Spirulina platensis* içeren örneklerin baharatlı yoğurt sosu gibi bir ürün olarak geliştirilebileceği belirtilmiştir.

**Anahtar Kelimeler:** Yoğurt, *Spirulina platensis*, *Lactobacillus acidophilus*

#### Sensory properties of classical and probiotic yogurt produced adding *Spirulina platensis*

##### Abstract

This study aims to determine the quality characteristics of the functional product obtained by enriching the yoghurt, an essential part of the human diet and frequently consumed daily, with *Spirulina platensis*, which stands out with its rich nutritional content and benefits for human health. For this purpose, 8 types of yoghurt, 4 classical and 4 probiotics, containing *Spirulina platensis* in 4 different ratios (0%, 0.3%, 0.6%, 0.9%) were produced. The sensory characteristics of the produced yoghurts were analyzed at 4 °C on the 1st, 7th, 14th, 21st and 28th days. The effect of *Spirulina platensis* powder in yogurt production on yogurt samples' sensory properties was significant. As a result of the sensory analysis, all of the yoghurt samples had scores between 4-5 out of 5 in terms of sensory evaluations (p<0.05). Considering all quality evaluations, a new enriched probiotic yoghurt with high nutritional value can be produced with *Lactobacillus acidophilus* and containing 0.3% *Spirulina platensis* (P0.3%). In addition, according to panellist evaluations, it was stated that the samples containing 0.9% *Spirulina platensis* could be developed as a product such as spicy yogurt sauce.

**Keywords:** Yogurt, *Spirulina platensis*, *Lactobacillus acidophilus*

## GİRİŞ

“Fonksiyonel Gıda” terimi; insanın metabolik fonksiyonları ve fizyolojisi için ilâve yararlar sağlayan gıda anlamına gelir. İnsan beslenmesinde ihtiyaç duyulan, temel besin maddelerinin alınması yanında, sağlıklı yaşamı desteklemede de etkileri vardır (Berner ve O'Donnell, 1998; Çakıroğlu ve Uçar, 2018). Gıdanın, fonksiyonel olarak nitelendirilebilmesi için prebiyotikler, probiyotikler ve biyoaktif bileşenleri yeterli miktarda içermesi ve tüketildiğinde beklenen faydayı sağlayabilmesi gerekir (Erbaş, 2006). Fonksiyonel gıdalar, insanın temel fizyolojisi, bağışıklık, sinir, hormon, solunum, dolaşım ve sindirim sistemlerinde olumlu etkiler oluşturarak birçok hastalığın oluşma risklerini azaltmaktadırlar (Litwin ve ark., 2018). Beslenme alışkanlıklarımız içerisinde tüketim oranı yüksek süt ve süt ürünleri, fonksiyonel bileşenler için iyi birer taşıyıcıdırlar. Bu nedenle, fonksiyonel süt ve süt ürünleri tüketimi, bireylerin yeterli ve dengeli beslenmesine

hizmet etmek yanında, gıda takviyeleri olarak günlük diyetle alımı çok tercih edilmeyen fonksiyonel bileşenler için de uygun bir kaynak oluşturmaktadır.

*Lb. acidophilus* ürettiği antimikrobiyal metabolitlerle ve besin bileşenlerini kullanarak patojenlerle rekabet eder ve bağırsak florasında bozulan dengeyi yeniden sağlar. Bu nedenle *Lb. acidophilus* tıp alanında ilgi duyulan bir bakteridir. Bu bakteri fekal enteropatojenik *E. coli* suşları ile *Salmonella* ve *Shigella* türlerine, *Proteus vulgaris* gibi diğer bağırsak patojenlerine karşı kuvvetli antibiyotik etki göstermesi bakımından laktik asit bakterileri arasında ayrı bir öneme sahiptir. Gastrointestinal sistemimizin doğal mikroflorasının dengesi birçok faktör nedeniyle bozulabilir. Bunlar çevre kirliliği, iklim değişiklikleri, ilaç kullanımı, yanlış beslenme ve stres gibi olumsuz faktörlerden oluşur. Bu etkenlere maruz kalan bireylerin, barsak sistemlerindeki dengesizlik, patojenlerin gelişimi ve beraberinde çeşitli hastalıklar için uygun zemin oluşturmaktadır. Vücutta istenilen sağlık yararının sağlanabilmesi için probiyotiklerin düzenli olarak tüketilmesi zorunludur. Tüketim esnasında ürünün probiyotik mikroorganizma sayısının en az  $10^6$ - $10^7$  kob/g seviyesinde olması gerekmektedir (Kailasapathy ve ark., 2008; Çakmakçı ve ark., 2012).

*S. platensis* en dikkat çekici yönü, yüksek protein içeriğidir. Ayrıca esansiyel yağ asidi, aminoasit, karotenoit, vitamin ve mineral bileşimi zengindir. Yüksek verimle elde edilebilmesi ticari üretimine başlanmasında önemli faktörlerden biridir. Ulusal Havacılık ve Uzay Dairesi ile Avrupa Uzay Ajansı uzay yolculuklarında ana yiyecek olarak belirlemiştir (Asghari, Fazilati, Latifi, Salavati, & Choopani, 2016). Birleşmiş Milletler ve Dünya Sağlık Örgütü (WHO) *S. platensis*'i çocuklar ve yetişkinler yüksek oranda yararlı gıda desteği olarak kabul etmektedir (Michaelsen vd., 2009). 2012 yılında *S. plantensis*'in güvenilirliği birçok toksikoloji araştırmaları ile ispatlanmıştır. Amerikan Gıda ve İlaç Dairesi (Food and Drug Administration, 2012) tarafından GRAS (Generally Recognised As Safe) listesine alınmıştır. Günlük 3-10 g tüketilmesi sağlık açısından önerilmiştir (Seyidoğlu ve ark., 2017).

Bu çalışmanın amacı, diyetimizin önemli bir parçası olup günlük hayatta sık sık tüketmiş olduğumuz yoğurdun, zengin besin içeriği ve insan sağlığına olan yararları bilinen *Spirulina platensis* ile zenginleştirilerek, kalite niteliklerinin artırılıp her yaşta tüketiciye fonksiyonel bir gıda olarak sunulabilir duruma getirmektir. Bu amaçla klasik ve probiyotik olmak üzere 2 tip (klasik ve probiyotik) yoğurda, farklı oranlarda (%0, %0,3, %0,6, %0,9) *Spirulina platensis* ilave edilerek toplamda 8 çeşit yoğurt üretilmiş, duyuusal kalite nitelikleri, 4 °C'de 1, 7, 14, 21 ve 28. günlerde analiz edilmiştir.

## MATERYAL VE METOT

### Deneme yoğurtlarının üretimi

Yoğurt örneklerinin üretiminde kullanılacak pastörize süt, 45-50 °C'ye arasında ön ısıtmaya tabi tutulmuştur. Yağsız kurumadde oranı en az %15 olacak şekilde önceden hesaplanan oranda yağsız süt tozu (YST) ve farklı oranlarda (%0, %0,3, %0,6, %0,9) *Spirulina platensis* ilave edilmiştir. 90 °C'de 5 dk süreyle ısıtma işlemi yapıldıktan sonra 43±2 °C'ye soğutulmuş bir gün önceden liyofilize *Streptococcus thermophilus* ve *Lactobacillus delbrueckii subsp. bulgaricus* ve *Lactobacillus acidophilus* LA-5® ana kültüründen hazırlanan aktive edilmiş bulk kültürler ile %2 oranında inokule edilmiştir. Yoğurt örnekleri 42±1 °C'de pH 4,7±0,1'e ulaşıncaya kadar inkübe edilmiştir. İnkübasyon tamamlandıktan sonra 4±1 °C'de 24 saat tutulmuştur. Depolamanın 1, 7, 14, 21 ve 28. günlerinde gerekli analizler yapılmıştır.

### Yoğurt örneklerinde yapılan duyuusal analizler

Duyuusal panellerde, Bodyfelt ve ark. (1988) ve TS 1330 (2009) tarafından verilen puantaj cetveli modifiye edilerek kullanılmıştır. Bu amaçla, yoğurt örneklerinin temel bazı organoleptik nitelikleri (dış görünüş, kıvam (kaşıkla), kıvam (ağızla), koku ve tat) depolamanın 1, 7, 14, 21 ve 28. günlerinde Gıda Mühendisliği Bölümü öğretim elemanlarından ve gıda mühendislerinden oluşan 10 kişilik gönüllü panelist grup tarafından her bir parametre için 5 puan, toplam 25 puan üzerinden değerlendirilmiştir.

### İstatistiksel analizler

Araştırma sonucunda edilen değerler IBM SPSS Statistic 22 paket programında varyans analizine tabi tutulmuş, analiz sonucunda önemli çıkan faktörler Duncan çoklu karşılaştırma testi ile %99 ( $p<0,05$ ) güven düzeyinde değerlendirilmiştir (SPSS, 2022).

## BULGULAR ve TARTIŞMA

### Yoğurt Örneklerine Ait Duyusal Analiz Sonuçları

#### Dış görünüş.

Yoğurt örneklerine ait dış görünüş puanları 3,70 ile 5,00 arasındadır. Yoğurt örneklerinde en yüksek dış görünüş puanları 5,00 ile depolamanın 1, 7, 14 ve 28. günlerinde KK, 14. günde KK ve 28. günde K%0,6 örneğinde; en düşük dış görünüş puanı 3,70 ile depolamanın 1. gününde K%0,6 örneğinde tespit edilmiştir. Klasik ve probiyotik yoğurt örneklerinde depolama süresince dış görünüş değerlerinde meydana gelen değişim Şekil 1'de görülmektedir

Şekil 1. Dış görünüş puanının depolama süresince değişimi

Dış görünüş değerlerine uygulanan varyans analizi sonucunda (Tablo 1), örnek değişkeninin dış görünüş puanı üzerine etkisi istatistiksel açıdan  $p < 0,01$  seviyesinde, depolama periyodunun etkisi ise  $p < 0,05$  seviyesinde önemli bulunmuştur. Örnek ve depolama değişkenlerinde, farklılığın kaynağını belirlemek amacıyla yapılan Duncan çoklu karşılaştırma test sonucu ise Tablo 2'de verilmiştir. Tablo incelendiğinde istatistiksel açıdan en yüksek ortalama değer klasik grupta ve probiyotik grupta yer alan ve *Spirulina platensis* ihtiva etmeyen kontrol örneklerinde (KK & PK) olduğu görülmektedir. İstatistiksel olarak K%0,3, K%0,6, P%0,3 örnekleri benzerlik göstermiştir ( $p > 0,05$ ). K%0,9, P%0,6 ve P%0,9 örnekleri de istatistiksel olarak benzerlik göstermiştir ( $p > 0,05$ ).

En yüksek ortalama dış görünüş puanı, istatistiksel olarak aralarında fark olmayan ( $p > 0,05$ ) 1, 7, 14 ve 28. depolama günlerinde görülürken, en düşük ortalama dış görünüş puanı 21. günde belirlenmiştir ( $p < 0,05$ ).

#### Kıvam (kaşıkla).

Yoğurt örneklerine ait kıvam (kaşıkla) puanları 4,10 ile 5,00 arasındadır. Yoğurt örneklerinde en yüksek kıvam (kaşıkla) puanları 5,00 ile depolamanın 14. günde KK örneğinde; en düşük kıvam (kaşıkla) puanı 4,10 ile depolamanın 7. gününde K%0,9 örneğinde tespit edilmiştir. Klasik ve probiyotik yoğurt örneklerinde depolama süresince kıvam (kaşıkla) değerlerinde meydana gelen değişim Şekil 2'de görülmektedir.

Şekil 2. Kıvam (kaşıkla) puanının depolama süresince değişimi

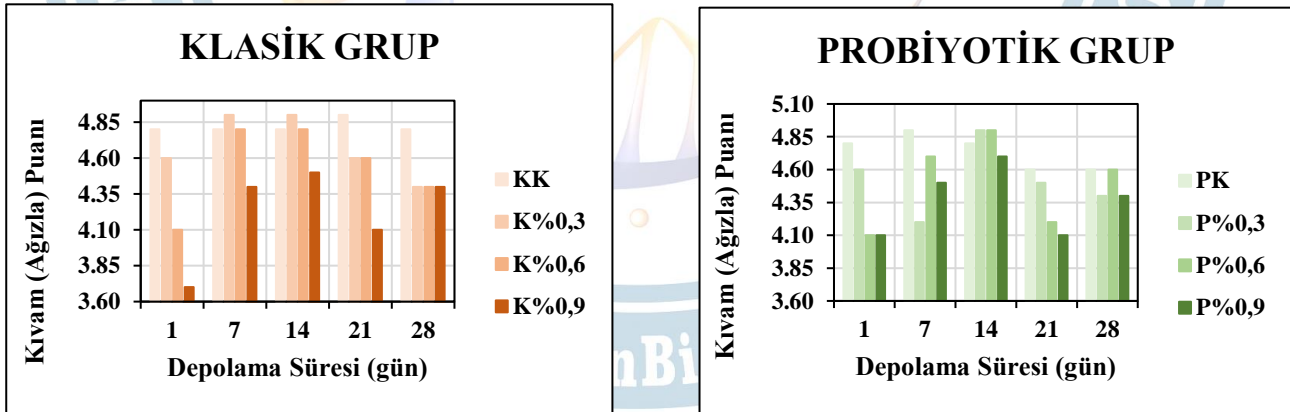

Kıvam (kaşıkla) değerlerine uygulanan varyans analizi sonucunda (Tablo 1), örnek değişkeninin kıvam (kaşıkla) puanı üzerine etkisi istatistiksel açıdan  $p < 0,01$  seviyesinde, depolama periyodunun etkisi ise  $p < 0,05$  seviyesinde önemli bulunmuştur. Örnek ve depolama değişkenlerinde, farklılığın kaynağını belirlemek amacıyla yapılan Duncan çoklu karşılaştırma test sonucu incelendiğinde (Tablo 2), istatistiksel açıdan en yüksek ortalama puanın probiyotik kontrol örneğinde (PK) olduğu görülmektedir. İstatistiksel olarak K%0,3 ve P%0,6 örnekleri benzerlik göstermiştir ( $p > 0,05$ ). En düşük ortalama puanın belirlendiği K%0,9 örneği ise istatistiksel olarak diğer örneklerden farklıdır ( $p < 0,01$ ).

En yüksek ortalama kıvam (kaşıkla) puanı depolamanın 14. günde görülürken, depolamanın diğer tüm günlerinde (1, 7, 21 ve 28. gün) benzerliğin olduğu ortaya çıkmıştır ( $p > 0,05$ ).

Kıvam (ağızla).

Yoğurt örneklerine ait kıvam (ağızla) puanları 3,70 ile 4,90 arasındadır. Yoğurt örneklerinde en yüksek kıvam (ağızla) puanları 4,90 ile depolamanın 7, 14 ve 21. günlerinde KK, K%0,3, PK, P%0,3 ve P%0,6 örneklerinde; en düşük kıvam (ağızla) puanı 3,70 ile depolamanın 1. gününde K%0,9 örneğinde tespit edilmiştir.

Klasik ve probiyotik yoğurt örneklerinde depolama süresince kıvam (ağızla) değerlerinde meydana gelen değişim Şekil 3'te görülmektedir.

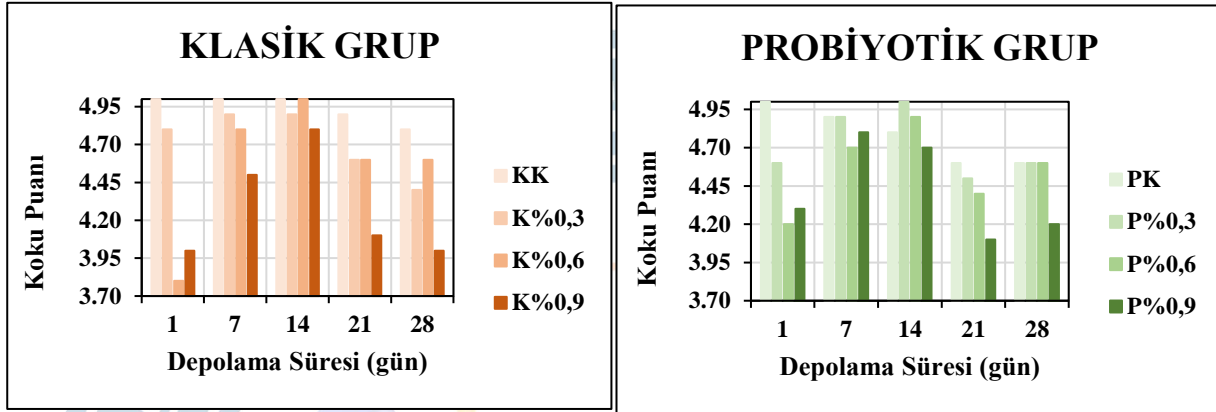

Şekil 3. Kıvam (ağızla) puanının depolama süresince değişimi

Yoğurt örneklerinin kıvam (ağızla) puanlarına ait varyans analiz sonuçları Tablo 1'de verilmiştir. Yapılan varyans analiz sonuçlarına göre, örnek değişkeninin ve depolama periyodunun etkisi kıvam (ağızla) puanı üzerine etkisi istatistiksel açıdan  $p < 0,01$  seviyesinde, önemli bulunmuştur. Duncan çoklu karşılaştırma test sonucu incelendiğinde (Tablo 2), istatistiksel açıdan en yüksek ortalama puanın klasik kontrol örneğinde (KK) olduğu görülmektedir. İstatistiksel olarak K%0,3, K%0,6 ve PK örnekleri; P%0,3 ve P%0,6 örnekleri kendi aralarında benzerlik göstermiştir ( $p > 0,05$ ). En düşük ortalama puan ise K%0,9 örneğinde çıktı ve istatistiksel olarak diğer örneklerden farklıdır ( $p < 0,01$ ).

En yüksek ortalama kıvam (ağızla) puanının depolamanın 14. gününde görülürken, depolamanın 21 ve 28. günlerinde benzerliğin olduğu ortaya çıkmıştır ( $p>0,05$ ). En düşük ortalama kıvam (ağızla) puanının depolamanın 1. gününde olduğu ve istatistiksel olarak diğer günlerden farklı çıktığı görülmüştür.

#### Koku.

Yoğurt örneklerine ait koku puanları 4,00 ile 5,00 arasındadır. Yoğurt örneklerinde en yüksek koku puanları 5,00 ile depolamanın 1, 7 ve 14. günlerinde KK ve PK örneklerinde; en düşük koku puanı 4,00 ile depolamanın 1 ve 28. günlerinde K%0,9 örneğinde tespit edilmiştir. Klasik ve probiyotik yoğurt örneklerinde depolama süresince koku değerlerinde meydana gelen değişim Şekil 4'de görülmektedir

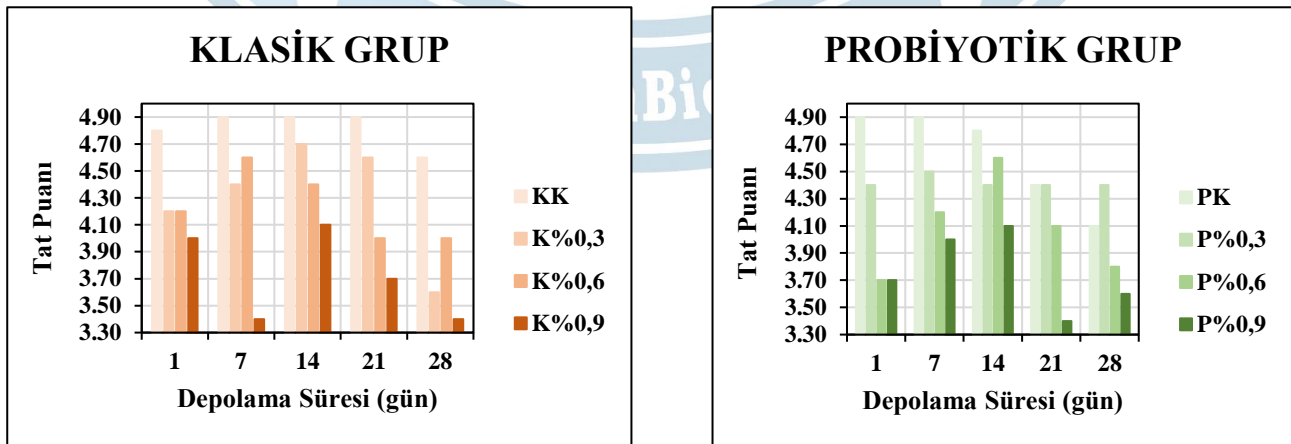

Şekil 4. Koku puanının depolama süresince değişimi

Koku puanlarına uygulanan varyans analizi sonucunda (Tablo 1), örnek değişkeninin ve depolama periyodunun koku puanı üzerine etkisi istatistiksel açıdan  $p<0,01$  seviyesinde önemli bulunmuştur. Örnek ve depolama değişkenlerinde, farklılığın kaynağını belirlemek amacıyla yapılan Duncan çoklu karşılaştırma test sonucu incelendiğinde (Tablo 2), istatistiksel açıdan en yüksek ortalama koku puanının klasik kontrol örneğinde (KK) olduğu görülmektedir. İstatistiksel olarak K%0,3, K%0,6, PK ve P%0,3 örnekleri kendi aralarında benzerlik göstermiştir ( $p>0,05$ ). En düşük ortalama değer ise K%0,9 örneğinde çıkmış ve istatistiksel olarak diğer örneklerden farklı bulunmuştur ( $p<0,01$ ).

En yüksek ortalama koku puanları depolamanın 7 ve 14. gününde görülürken, depolamanın 1, 21 ve 28. günlerinde benzerliğin olduğu tespit edilmiştir ( $p>0,05$ ) ve en düşük ortalama koku değerinin depolamanın 28. gününde olduğu tespit edilmiştir ( $p<0,01$ ).

#### Tat.

Yoğurt örneklerine ait tat puanları 3,40 ile 4,90 arasındadır. Yoğurt örneklerinde en yüksek tat puanları 4,90 ile depolamanın 1, 7, 14 ve 21. günlerinde PK ve KK örneklerinde; en düşük tat puanı 3,40 ile depolamanın 7, 21 ve 28. günlerinde K%0,9 ve P%0,9 örneklerinde tespit edilmiştir. Klasik ve probiyotik yoğurt örneklerinde depolama süresince tat değerlerinde meydana gelen değişim Şekil 5'de görülmektedir

Şekil 5. Tat puanının depolama süresince değişimi

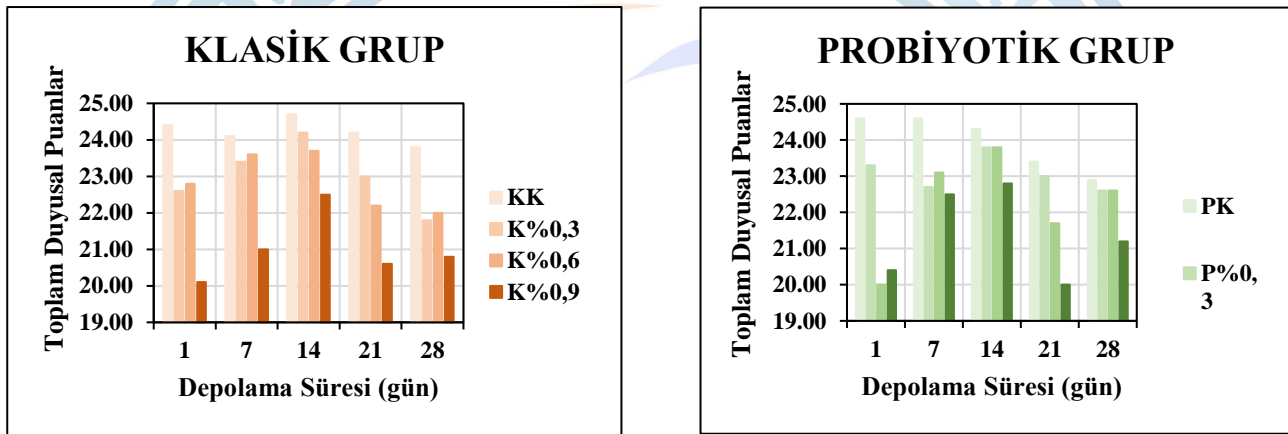

Tat puanlarına uygulanan varyans analizi sonucunda (Tablo 1), örnek değişkeninin ve depolama periyodunun tat puanı üzerine etkisi istatistiksel açıdan  $p < 0,01$  seviyesinde, önemli bulunmuştur. Örnek ve depolama değişkenlerinde, farklılığın kaynağını belirlemek amacıyla yapılan Duncan çoklu karşılaştırma test sonucu incelendiğinde (Tablo 2), istatistiksel açıdan en yüksek ortalama puanın 4,82 ile klasik kontrol (KK) örneğinde olduğu görülmektedir. İstatistiksel olarak K%0,3 ve K%0,6; K%0,9 ve P%0,9 örnekleri kendi aralarında benzerlik göstermiştir ( $p > 0,05$ ). En düşük ortalama değer ise 3,72 ile K%0,9 örneğinde çıkmıştır. Geriye kalan örnekler de kendi aralarında ve diğer tüm örneklerden istatistiksel olarak farklı çıkmıştır ( $p < 0,01$ ).

En yüksek ortalama tat puanının 4,50 ile depolamanın 14. gününde görüldüğü; depolamanın 1 ve 21. günlerinde benzerliğin olduğu ortaya çıkmıştır ( $p > 0,05$ ). En düşük ortalama tat değerinin 3,94 ile depolamanın 28. gününde olduğu tespit edilmiştir.

#### Toplam Duyusal Analiz Puanları.

Yoğurt örneklerine ait toplam duyuşsal analiz puanları 20,00 ile 24,70 arasındadır. Yoğurt örneklerinde en yüksek toplam duyuşsal analiz puanları 24,70 ile depolamanın 14. günü KK örneğinde; en düşük toplam duyuşsal analiz puanı 20,00 ile depolamanın 1 ve 21. günlerinde P%0,6 ve P%0,9 örneklerinde tespit edilmiştir. Klasik ve probiyotik yoğurt örneklerinde depolama toplam duyuşsal analiz puanlarında meydana gelen değişim Şekil 6'da görülmektedir.

Şekil 6. Toplam duyuşsal analiz puanının depolama süresince değişimi

Toplam duyuşsal analiz puanlarına uygulanan varyans analizi sonucunda (Tablo 36), örnek değişkeninin ve depolama periyodunun tat puanı üzerine etkisi istatistiksel açıdan  $p < 0,01$  seviyesinde, önemli bulunmuştur. Örnek ve depolama değişkenlerinde, farklılığın kaynağını belirlemek amacıyla yapılan Duncan çoklu karşılaştırma test sonucu incelendiğinde (Tablo 2), istatistiksel açıdan en yüksek ortalama puanın 24,24 ile klasik kontrol (KK) örneğinde olduğu görülmektedir. İstatistiksel olarak K%0,3 ve P%0,3 örnekleri kendi aralarında benzerlik göstermiştir ( $p > 0,05$ ). En düşük ortalama değer ise 21,00 ile K%0,9 örneğinde çıkmıştır. Geriye kalan örnekler de kendi aralarında ve diğer tüm örneklerden istatistiksel olarak farklı çıkmıştır ( $p < 0,01$ ). En yüksek ortalama toplam duyuşsal analiz puanlarının 23,73 ve 23,12 ile depolamanın 7 ve 14. günlerinde görüldüğü ve aralarında istatistiksel olarak benzerliğin ( $p > 0,05$ ) olduğu; en düşük ortalama toplam duyuşsal analiz puanının 22,21 ile depolamanın 28. gününde olduğu tespit edilmiştir. 1, 21 ve 28. günler de kendi aralarında benzerlik taşıdığı görülmektedir ( $p > 0,05$ ).

**Tablo 1.** Yoğurt örneklerinin duyuşsal niteliklerinin varyans analiz sonuçları

## SONUÇ

Yoğurt örneklerinin, depolama periyodu süresince 1, 7, 14, 21 ve 28. günlerde duyuşsal nitelikleri; dış görünüş, kıvam (kaşıkla), kıvam (ağızla), koku ve tat parametreleri ile toplam duyuşsal puanlar üzerinden değerlendirilmiştir. *Spirulina platensis* ilavesi ve depolama periyodunun tüm duyuşsal parametreler üzerine etkisi istatistiksel açıdan (p<0,01; p<0,05) önemli bulunmuştur. *Spirulina platensis* ilavesi tüm örneklerde duyuşsal puanları zayıflatsa da ortalama puanlar tüm gün ortalamalarında hiçbir örnekte 4 puanın altına düşmemiştir. Tüm parametrelerde en yüksek ortalama puanlar klasik grup örneklerde ve depolamanın 14. gününde belirlenmiştir. Duyuşsal analiz sonuçlarına göre kontrol örnekleri dışında en çok beğenilen ürün *Spirulina platensis* içeriği %0,3 olan probiyotik ve klasik yoğurt örnekleridir. *Spirulina platensis* miktarındaki artış, tat ve aromadaki artışa da doğrudan etki ettiğinden %0,6 ve %0,9 *Spirulina platensis* içeren örnekler %0,3 *Spirulina platensis* ihtiva eden örneklere göre daha düşük puan almışlardır. Fakat toplam skor 21 puanın (toplam duyuşsal analiz) altına düşmemiştir. Duyuşsal analiz sonuçları, depolamanın 21. gününe kadar tüm örneklerin duyuşsal genel kabul edilebilirlik açısından uygun olduğunu göstermektedir. Yüksek ihtimalle yosun tadından dolayı tercih edilmeyen bu zengin bileşimli ucuz besin ve enerji kaynağının ülkemiz insanının damak tadına hitap edecek şekilde formülasyonlarla gıda sektörüne kazandırılması önem arz etmektedir.

## Teşekkür:

Bu çalışma, Doç. Dr. Ayla ARSLANER danışmanlığında Çağrı GÜLER tarafından tamamlanan “*Spirulina platensis* ilaveli probiyotik (*Lactobacillus acidophilus*) yoğurtların bazı kalite nitelikleri ve probiyotik raf ömrü” başlıklı Yüksek Lisans Tezi’nin bir bölümünden üretilmiştir.

#### Özet

Türkiye’de tıbbi aromatik bitkiler denildiğinde aklımıza ilk gelen Ege Bölgesi ve Akdeniz Bölgesi kıyılarında yoğun olarak yetiştirilip (Bağdat, 2006), kültürü yapılan *Salvia off.* Geleneksel-tamamlayıcı tıp ve ticari açıdan kullanımları gün geçtikçe artmaktadır (Abreu ME, 2008). Bu özelliği ile bilim camiasının dikkatini yoğun bir şekilde çekmektedir. Geleneksel açıdan birçok terapötik etkisinden dolayı örneğin: Antioksidan, antikanser, asetil-kolinesteraz, bütil-kolinesteraz (Elmas S. ve Elmas O., 2021) tercih edilen *Salvia off.* cinsi bitkisinin literatürde fitokimyasal açıdan birçok araştırma konusu olduğu görülmüştür.

Bu çalışma kapsamında ticari adıyla adaçayı otunun biyolojik aktivite olarak antioksidan aktivitesine moleküler düzeyde anlam kazandırmak amaçlanmış ve GC/MS analizleri yapılarak ardından bu analiz sonuçlarında aydınlatılan bileşiklerin *in silico* olarak moleküler docking çalışmalarıyla desteklenebilirliği ortaya konuldu.

**Anahtar Kelimeler:** Antioksidan aktivite, *Salvia officinalis* , Moleküler modelleme

#### **Phytochemical elucidation of *Salvia officinalis* plant by GC/MS method and evaluation of it is *in silico* antioxidant activity**

#### Abstract

When we think of medicinal aromatic plants in Turkey, the first thing that comes to mind is *Salvia off.* *Salvia*, which is intensively cultivated and cultivated in the Aegean and Mediterranean coasts (Baghdad, 2006), and its traditional-complementary medicine and commercial uses are increasing day by day (Abreu ME, 2008). With this feature, it attracts the attention of the scientific community intensively. Due to its many traditional therapeutic effects, such as: Antioxidant, anticancer, acetyl-cholinesterase, butyl-cholinesterase (Elmas S. and Elmas O., 2021), *Salvia off.* has been the subject of many phytochemical studies in the literature.

Within the scope of this study, it was aimed to give meaning to the antioxidant activity of sage as a biological activity at the molecular level and GC / MS analyzes were performed and then the supportability of the compounds illuminated in these analysis results by molecular docking studies *in silico* was revealed.

**Keywords:** Antioxidant activity, *Salvia officinalis* , Molecular modeling

#### YÖNTEM

Ekstraksiyon Süreci:

Toplanan ve teşhis işlemi yapılan bitkinin toprak üstü kısımları gölgede kurutularak drog elde edildi. Bir öğütücüde uygun toz haline getirildi. Toz drog kalıntıları su, etanol, hekzan ve etil asetat çözücülerinde günde 8 saat olmak üzere 3 gün boyunca mukayese edildi. Ekstraksiyon işleminden sonra fraksiyonlar birleştirildi ve ekstrakt 40°C’de düşük basınç altında kurutuldu.

GC-MS Analizi:

Numune hazırlama aşamasında *Salvia off.* cinsinin ekstresinin tayini için analizden önce iki aşamalı türevlendirme yapıldı. Türevlendirmenin ilk aşaması için, analizden önce ekstrelerin sililenmiş türevi ve metoksiamin muamele edildi. Kromatogramda çoklu kromatografik heterozitlerin piklerini önlemek için metoksiamin kullanıldı. Metoksiaminleme işleminden önce, günlük olarak piridin (25 mg/ml) içinde metoksiamin hidroklorür (MOX) (Sigma-Aldrich, Almanya) çözeltisi hazırlandı. 100 µl numune hafif nitrojen akışı altında buharlaştırıldıktan sonra kurutulmuş numuneye 50 µl MOX solüsyonu ilave edilerek 30°C derecede 90 dakika bekletildi. Daha sonra 50 µl BSTFA + %1 TMCS (Sigma-Aldrich, Germany) eklendi ve aktif grupların korunmasını sağlamak amacıyla 70°C'de 45 dakika daha tutuldu.

Enstrümantal analiz için thermoscientific ISQ 7000 Single Quadrupole GC-MS System marka cihaz kullanıldı. Analitik kolon olarak teknokroma marka gaz kromatografisi kılcal kolonu kullanıldı. Taşıyıcı olarak distile su, etanol, etil asetat gazı kullanıldı. Kör numune olarak sadece türevlendirilmiş bir numune enjekte edildi. GC fırın sıcaklığı 50°C'de başladı ve 2 dakika tutuldu, ardından 3°C/dk'da 280°C'ye yükseltildi ve 12 dakika tutuldu. Total sürüklenme zamanı 90 dk sürdü. Kütle spektrumu, 70 eV'de elektron iyonizasyonu ile elde edildi. Dedektör tarafından 50-500 atomik kütle birimi tarandı. Bileşikleri belirlemek ve tanımlamak için Mass Hunter yazılımı (Qualitative Analysis B.07.00) ve NIST Mass Spectral Library (2014) kullanıldı.

#### Moleküler Modelleme Çalışmaları:

İlk olarak *Salvia off.* cinsi bitkinin fitoterapideki kullanımına bağlı literatür taraması yapılarak hangi biyolojik aktivitenin daha çok bitkiyle ilişkilendirildiği sonucu araştırılarak, bu tarama sonucunda antioksidan aktivitenin çalışılmasına karar verildi ve uygun protein seçilimi yapıldı. Bu protein seçiminde PDB:6F7Q belirli saflaştırma özelliklerine göre elenerek çalışılacak protein olarak seçim yapıldı. PDB:6F7Q proteini daha önce Noshadi ve arkadaşlarının yapmış oldukları çalışmadaki hedef bölgesi baz alınarak çalışıldı (Noshadi et al., 2020). Hedef bölgedeki aminoasitler Tyr332, Phe329, Leu286, Trp231, Gly116, Glu197, Trp82 bilgisine Noshadi ve arkadaşının yapmış olduğu şekil 2'deki verilerden ulaşıldı (Noshadi et. all., 2020).

*Salvia off.* cinsinde GC-MS (gaz-kromatografisi) sonuçlarına göre farklı ve potansiyel olabilecek bileşikler 2D yapısı çizilerek ligandlar oluşturuldu. Daha sonra docking çalışması için Glide-2021(Schrödinger ©) arayüzü kullanıldı. Birinci adımda protein hazırlama yapıldı. A zinciri hariç diğer zincirler ve suların tümünün dışlanmasıyla OPLS\_2005 işlemi yapıldı. Hedefin bağlanacağı ızgara alanı oluşturulurken spesifik aminoasitlerimizin bulunduğu yüzeyin olması sağlandı. İkinci aşama olarak LigPrep aşaması 2D olarak çizilen bileşiklerin seçilerek OPLS\_2005 kuvvetine göre hazırlandı. Üçüncü aşama olarak docking aşaması için uygun koşullar seçilerek LigDock yapılarak görüntü ve sonuçlar elde edildi.

GC/MS aydınlatma sonuçlarına göre şekil 1 ve şekil 2'deki kromatogram verilerinden tablo 1'de derlenen bileşiklerin varlığı saptanmış ve biyolojik aktivite aydınlatılması için hazır hale getirilmiştir.

*In silico* biyolojik aktivitede yorum yapılmasını kolaylaştırmak amacıyla gallik asit bileşiği (Sousa, J. N., Queiroz, L. D. R. P., vd.,2023) referans olarak belirlenip kullanılmıştır.

**Tablo 2.** Moleküler modelleme sonuçları

Bileşik Adı	Glide Energy	Docking Skore
Gallik asit	-25.269	-5.494
Karvakrol	-21.882	-4.672
2-isopropil-5-metil-hidrokinon	-19.742	-4.552
4-isopropil-3-metil-fenol	-21.566	-4.301
2,2-dimetil-3-metilen-norbornan-1,4-dikarboksilik asitin dimetil esteri	-24.047	-4.062
5-isopropil-2-metil-bisiklo[3.1.0]heks-2-en	-15.458	-3.594
(1R,4E,9S)-4,11,11-trimetil-8-metilen-bisiklo[7.2.0]undek-4-en	-18.919	-3.496
2,6,6-trimetilbisiklo[3.1.1]hept-2-en	-14.598	-3.291
7-metil-3-metilen-okta-1,6-dien	-16.640	-2.315

Tablo 2'de verilmiş olan verilere göre referans bileşik olan gallik asite oranla docking skoreu mutlak olarak en yakın olan karvakrol ve ardından gelen 2-isopropil-5-metil-hidrokinon bileşiğidir. Glide enerjileri tüm incelenen moleküllerde ortalama olarak aynı düzeydedir anlamlı bir fark gözlenmemiştir. Docking skoredan anlaşıldığı üzere aktivitede belirleyici faktör olma ihtimali yüksektir. Anlamlı korelasyon DPPH aktivite deneyi laboratuvar koşullarında gerçekleştiğinde yapılabilir.

Şekil 3. Referans bileşik olan gallik asidin ligand etkileşim diyagramı

Şekil 4. Belirlenen bileşiklerin ligand etkileşimleri

Şekil 5. Belirlenen bileşiklerin ligand etkileşimleri

Şekil 4 ve 5 de verilen ligand interaktionlar için docking skore verisiyle hidrojen bağı yakalanan aminoasit sayısı ile orantı olabileceği sonucu ortaya çıkmıştır. Karvakrol gibi hidroksilce zengin bileşiklerde bağ yakalanma aktivite açısından önem teşkil ettiği gözlenmektedir.

Tüm bu veriler sonucunda *Salvia off.* tıbbi kültürü yapılarak antioksidan preparatı olarak farmakoeconomik açıdan uygun olmasa da başka etkinlikler için umut vaat edici özellikleri olabileceği tartışma konusu olmuş olup başka çalışmalar için esin kaynağı olabileceği ortaya çıkmıştır.

#### Özet

Kayseri ili sınırları içerisinde yer alan Erciyes Dağı'ndan 2018-2020 yıllarının Mayıs - Eylül ayları arasında yapılan arazi çalışmalarında Gnaphosidae familyasına ait örümcek örnekleri toplanmıştır. Toplanan örneklerin tür teşhisleri sonucunda 16 cinse ait 29 türün varlığı ortaya konmuştur. En çok tür tespit edilen cinsler sırasıyla *Drassodes*, *Micaria* ve *Haplodrassus* cinsleridir.

**Anahtar Sözcükler:** Gnaphosidae, fauna, Erciyes Dağı, örümcek, yer örümcekleri

#### Ground spiders (Araneae: Gnaphosidae) Fauna of Erciyes Mountain (Kayseri)

#### Abstract

Spider specimens belonging to the family Gnaphosidae were collected from Mount Erciyes in Kayseri province between May and September 2018-2020. Species identification of the collected specimens revealed the presence of 29 species belonging to 16 genera. The genera with the highest number of species were *Drassodes*, *Micaria* and *Haplodrassus*, respectively.

**Keywords:** Gnaphosidae, Fauna, Erciyes mountain, Spider, Araneae

#### Giriş

Arthropoda (Eklembacaklılar) şubesi içerisinde yer alan örümcekler, örümceğimsiler (Arachnida) sınıfına dâhildir ve biyolojik çeşitlilik bakımından oldukça zengin olan takımlarından birini oluşturur. Prosoma ile opistosoma'nın pedisel ile birleşik olması, erkeklerinde çiftleşme organının pedipalpler üzerinde bulunması ve opistosoma bölgesinde ağ bezi kabartılarının varlığı gibi özelliklere sahip olmalarıyla örümcekler diğer araknid gruplarından kolayca ayrılırlar (Foelix, 2011).

Örümcekler, Dünya'da 135 familya, 4335 cins, 51372 tür (World Spider Catalog, 2023), ülkemizde ise 55 familya, 370 cins, 1255 tür ile temsil edilmektedirler (Seyyar ve Demir, 2017; Danışman vd., 2023).

Ülkemizde yayılış gösteren örümceklerin büyük bir kısmını yer örümcekleri oluşturmaktadır. Gnaphosidae familyası 34 cinse ait 162 türle hem cins hem de tür sayısı bakımından ülkemizde ilk sırada yer alır (Danışman vd., 2023).

Gnaphosidae familyasına ait örümcekler siyah, koyu kahverengi veya griden yeşile kadar değişen renklerde, genellikle 1 ila 15 mm uzunluğunda ve iki tırnaklı bacaklara sahiptirler. Bazılarının sırt ve karın bölgelerinde desenler vardır. Ayrıca, familya üyelerinde gözlerin konumu ve büyüklüğü, labiyumun ve enditlerin şekli gibi önemli karakteristik özellikleri arasındadır. Bu yer örümceklerini diğer akraba familyalardan ayıran en önemli özelliği ise ön ağ bezi kabartılarının ayrık, silindirik şekilli ve uçlarının küt bir şekilde sonlanmasıdır (Platnick, 1978).

Gnafozidler genellikle 1–15 mm uzunluğunda, bacakları iki 2 tırnaklı, genellikle desenlenme göstermeyen örümceklerdir. Genellikle toprakta, taş altlarında, ağaç kabuklarında, kaya çatlaklarında veya kurumuş yaprak döküntüleri arasında yaşarlar ve buralarda tüp şeklinde ağlar örerler (Beccaloni, 2009; Foelix, 2011).

**Şekil 2.** Arazi çalışmalarında kullanılan ekipmanlar (Pens, şemsiye ve aspiratör).

Muhafaza edilerek laboratuvara getirilen örnekler öncelikle Gnaphosidae familyasına ait olanları belirlemek amacıyla, familya düzeyinde teşhisleri yapılarak ayıklandı. Örneklerin cins ve tür teşhislerinde müze materyalleri ve literatür bilgilerinden faydalanıldı.

### **Bulgular**

Araştırma alanından toplanan örneklerin faunistik değerlendirilmesi sonucunda Gnaphosidae familyasından 16 cinse ait 29 tür tespit edilmiştir. Türlerin eşey durumlarına göre dağılımları aşağıda Çizelge 1’de verilmiştir.

Çizelge 1. Çalışma alanından toplanan türler ve eşey durumları

TÜR LİSTESİ ve EŞEY DURUMLARI

### Sonuç ve Tartışma

Araştırma alanından toplanan örneklerin faunistik değerlendirilmesi sonucunda Gnaphosidae familyasından 16 cinse ait 29 tür tespit edilmiştir. Bu türlerden *Marjanus platnicki* (Zhang, Song & Zhu, 2001) türü son zamanlarda sadece ülkemizde Erciyes Dağı'nda tespit edilmiş bir türdür (Seyyar vd., 2019). Erciyes Dağı'ndan daha önce Nosek tarafından tespit edilmiş olan *Drassodes lutescens* (C. L. Koch, 1839), *D. similis* Nosek, 1905, *Drassodes pubescens* (Thorell, 1856), *Haplodrassus signifer* (C. L. Koch, 1839), *Gnaphosa lucifuga minor* Nosek, 1905, *Zelotes longipes*, *Z. atrocaeruleus* türlerini tanımlanmıştır (Nosek, 1905).

Yapılan arazi çalışmaları sonucunda bu türlerden 4 tanesi yeniden Erciyes Dağında rastlanılmıştır. En çok türü bulunduran cins 5 türle *Drassodes* cinsi olup bunu sırasıyla 3 türle *Micaria* ve *Haplodrassus* cinsleri takip etmektedir (Şekil 3).

Şekil 3. Erciyes Dağı'nda tespit edilen cinslerin türlere göre dağılımı

#### Abstract

Kombucha is a fermented beverage. Its consumption has significantly increased during the last decades due to its perceived beneficial effects. For this reason, it has become a highly commercialized drink that is produced industrially. During fermentation, pH, which determines acidity, is very important. The aim of this study was to determine the pH changes during fermentation at different temperatures and to investigate which temperature should be preferred for safe consumption. For this purpose, kombucha samples prepared with green tea were fermented at 20, 24, 28 and 32°C 16 days. pH measurements were made every 2 days. It was determined that the most suitable pH for optimum consumption was fermentation at 24 and 28°C.

**Keywords:** Kombucha, fermentation, pH, green tea, beverage

#### INTRODUCTION

Kombucha is a traditional fermented tea that has gained popularity due to its potential health benefits. It is rich in organic acids, minerals, vitamins, proteins, polyphenols, and other beneficial compounds. These compounds contribute to the various therapeutic properties of kombucha, including its antioxidant, antimicrobial, and antifungal activities (Mousavi et al., 2020). Scientific studies have shown that kombucha has potential anticancer effects and may enhance resistance to cancer (Watawana et al., 2015). The beverage has also been found to have hepatoprotective effects (Mousavi et al., 2020).

The fermentation process of kombucha involves a symbiotic culture of bacteria and yeast, known as SCOBY (Nizioł-Lukaszewska et al., 2020). This fermentation process leads to the production of bioactive compounds, such as antioxidants, which contribute to the health benefits of kombucha (de Miranda et al., 2022). Kombucha has been found to have high antioxidant activity, mainly attributed to its phenolic compounds. These phenolic compounds are responsible for the supposed health benefits of the beverage (Miranda et al., 2022)(de Miranda et al., 2022).

Furthermore, kombucha has been investigated for its potential as a probiotic. It has been found to have a broad microbial diversity, including probiotic bacteria and yeasts (Kaashyap et al., 2021). These microorganisms have been shown to have health benefits for the human gut, suggesting that kombucha can act as a powerful probiotic (Kaashyap et al., 2021). The presence of probiotics in kombucha contributes to its potential for improving gut health and overall well-being.

However, it is important to note that while kombucha has many potential health benefits, there are also risks associated with its consumption. Some health risks and side effects have been reported, including the presence of biological and chemical hazards (Kim and Adhikari, 2020). Therefore, it is important to ensure the safety and quality of kombucha products through proper manufacturing practices and food safety measures (Kim and Adhikari, 2020).

The aim of this study was to determine that the pH values of kombucha samples fermented with green tea at different temperatures at the end of the fermentation period are suitable for safe consumption.

## MATERIALS AND METHODS

Green tea leaves and starter culture were collected from local shop in the Türkiye. The green tea broth was prepared by adding 7 g of green tea leaves to boiling water. After 30 min, the tea leaves were sieved and 70g of sucrose was added to prepare sugared green tea. Then, 1000 mL of sugared green tea was poured into a 2000 mL bottle, a 10% (v/v) starter culture was added. The bottle was covered with a cloth sheet and secured with rubber bands, then it was incubated for 16 days under aerobic conditions at temperatures ranging from 20°C to 32°C. pH values were measured and recorded every 4 days. The measurements were made in 3 parallels and averaged.

## RESULTS AND DISCUSSION

In this study, it was aimed to determine the effect of temperature changes on pH changes during Kombucha fermentation. For this, a 14-day fermentation process was used. The pH values recorded as a result of the fermentation process are shown in Table 1.

**Table 1.** pH values measured during the fermentation period

Kombucha Fermentation	0 <sup>th</sup> day	4 <sup>th</sup> day	8 <sup>th</sup> day	12 <sup>th</sup> day	16 <sup>th</sup> day
Kombucha at 20°C	6.74±0.12	6.35±0.08	6.01±0.04	5.57±0.04	5.31±0.08
Kombucha at 22°C	6.74±0.12	6.21±0.07	5.89±0.05	5.06±0.04	4.61±0.07
Kombucha at 24°C	6.74±0.12	5.99±0.08	5.10±0.05	4.23±0.05	3.74±0.06
Kombucha at 26°C	6.74±0.12	5.87±0.06	4.92±0.07	3.95±0.05	3.45±0.07
Kombucha at 28°C	6.74±0.12	5.80±0.08	4.90±0.06	3.85±0.03	3.30±0.07
Kombucha at 30°C	6.74±0.12	5.74±0.07	4.81±0.05	3.72±0.03	3.01±0.06
Kombucha at 32°C	6.74±0.12	5.70±0.05	4.69±0.04	3.48±0.04	2.87±0.05

Table 1 shows the pH change during fermentation depending on the temperature. At the end of the 14<sup>th</sup> day of fermentation at 20°C, the pH value was determined as 5.31±0.08. This value is the highest pH value obtained. this pH value is suitable for consumption. However, it is insufficient for the completion of kombucha fermentation. In addition, the pH value was measured as 2.87±0.05 as a result of fermentation at 32°C. This is the lowest pH value among all samples. this value is harmful for kombucha consumption. kombucha samples consumed at this pH are known to be harmful to the human stomach (Vitas et al., 2018).

Coskun and Kayisoglu, (2020) carried out kombucha fermentation using different plant samples. In their study, they reported that the optimum temperature for pH values was 24°C. Deghrigue et al., (2013) also carried out fermentation using a temperature of 25°C for kombucha fermentation. Fu et al., (2014) used a temperature of 30°C for kombucha fermentation of black tea. They ended the fermentation on the 8<sup>th</sup> day. In 8 days they reached the optimum pH level. The optimum fermentation time for traditionally prepared kombucha is 14 days. On the 8<sup>th</sup> day, they terminated the fermentation because they reached a low pH value that could be consumed. However, they did not reach the 14<sup>th</sup> day, which is the appropriate fermentation period for kombucha. This showed that the pH value decreased very quickly at 30°C. This study is in parallel with the results we obtained in this aspect. Gaggia et al., (2019) used 28 degrees Celsius for fermentation temperature in their study. They measured pH on the 7<sup>th</sup> and 14<sup>th</sup> day. The result they obtained shows that kombucha fermentation takes place successfully. The pH measurements obtained with the temperatures used in the study are in parallel with our results.

As a result, different temperatures are used for kombucha fermentation. However, according to the results obtained, pH values suitable for human consumption differ. In this respect, it is suggested that the optimum pH range for kombucha consumption is between 3.74 and 3.30. In our results, it is seen that this pH range is reached at 24, 26 and 28°C.

## CONCLUSION

In conclusion, kombucha is a fermented drink widely consumed among people. pH is important for the human stomach in the consumption of this fermented beverage. As a result of 14 days of fermentation, it was revealed with the results we obtained that the appropriate temperature for kombucha, which is ready for consumption, is between 24 and 28°C. The results we obtained were useful in obtaining preliminary information to reveal the importance of kombucha consumption in terms of pH for the human stomach. It has contributed to the literature in terms of other effects that kombucha samples consumed in this pH range may cause in terms of human stomach health. It is recommended that studies using human subjects be conducted to obtain more detailed information.

#### Abstract

Spiders are the most successful of the arachnids (Arachnida) class of arthropods (Arthropoda), adapted to terrestrial ecosystems. Spiders have many enemies. Especially non-web-building spiders have many natural enemies during hunting. In this study, the similarities or differences between web-building and non-web-building spider species were examined by comparing total protein and total RNA levels and by performing biochemical analyses at the molecular level to obtain preliminary information on protein and gene structure of spider species with different hunting strategies through transcriptional and translational approaches. Total protein and total RNA measurements were analyzed for this study. As a result, it was determined that spiders hunted by making webs contained more total protein and total RNA than spiders hunted without making webs.

**Keywords:** Spider, total protein, total RNA

#### INTRODUCTION

Spiders are adapted to many of the world's ecosystems and therefore have a wide range of distribution across the globe. There have been many studies on spiders with different hunting strategies and ecological niches (Foelix, 2011). Studies on spiders, which have been the center of attention in the last 50 years, are mostly faunistic, systematic and ecological (Beccaloni, 2009). The number of molecular and biochemical studies on spiders is remarkably low, and these studies are mostly concerned with the detailed structure of spider webs and their silk. Spider silk produced by different spiders may have different composition and properties.

After protein synthesis, reactions such as phosphorylation and methylation play an important role in the functionalization of proteins and important biological molecules such as nucleic acids. Post-synthesis modifications of proteins make them important in signal transduction and enable a rapid and organized sequential collective response to extracellular events. The interaction of proteins plays an important role in many key cellular events including regulation of transcription (Clarke, 2003), cellular stress response, protein repair and aging (Kujubu et al., 1993), T cell activation (Cimato et al., 1997), nuclear transport (Vemuri and Philipson, 1988), neuronal differentiation ion channel function, cytokine signaling (Chen et al., 2004).

RNA analysis is important in determining the responses of organisms to different environmental conditions at the molecular level. RNA analysis provides preliminary information in determining the properties of proteins produced in organisms with different living conditions.

In this study, in order to obtain preliminary information on the transcriptional and translational expression and gene and protein size of spider species with different hunting strategies, total RNA and total protein levels were compared to determine the similarities or differences between different species at the molecular level.

## MATERIALS AND METHODS

In this study, *Araneus quadratus* and *Araneus diadematus* spider species, which are hunted by making webs, and *Alopecosa pulverulenta* and *Drassodes lapidosus* spider species, which are hunted without making webs, were obtained from nature and identified in the laboratory.

For homogenization of spiders, 0.1 g of sample was homogenized in 10 mL of 2 mM (pH: 7.4) phosphate buffer for 5 min. After homogenization, the samples were centrifuged at 10000 rpm for 5 min and 1 mL of the supernatant in the tubes was placed in sterile ependorf tubes and kept at +4°C.

The method proposed by Lowry was used to determine the amount of protein in 1 µL of supernatants from spider species (Lowry et al., 1951). Total RNA elution was performed according to the method of Chomczynski and Sacchi (Chomczynski and Sacchi, 1987).

## RESULTS AND DISCUSSION

Lowry method was used to determine the protein content of the supernatants obtained from spider species. The total protein and RNA results we obtained are shown in Table 1. The protein content of *A. quadratus*, one of the spider species hunted by making webs, was  $0.287 \pm 0.023$  ng/µL and the protein content of *A. diadematus*, another spider species hunted by making webs, was  $0.251 \pm 0.018$  ng/µL. The protein content of *A. pulverulenta*, a spider species that hunts without making a web, was  $0.122 \pm 0.007$  ng/µL and the protein content of *D. lapidosus*, another spider species that hunts without making a web, was  $0.151 \pm 0.008$ .

**Table 1.** Total protein and RNA results of the samples

Spider species	Total protein (ng/µL)	Total RNA (ng/µL)
<i>Araneus quadratus</i>	$0,287 \pm 0,023$	$0,280 \pm 0,014$
<i>Araneus diadematus</i>	$0,251 \pm 0,018$	$0,214 \pm 0,023$
<i>Alopecosa pulverulenta</i>	$0,122 \pm 0,007$	$0,084 \pm 0,009$
<i>Drassodes lapidosus</i>	$0,151 \pm 0,008$	$0,107 \pm 0,008$

The total RNA content of *A. quadratus*, one of the spider species that hunts by making webs, was  $0.280 \pm 0.014$  ng/µL and the total RNA content of *A. diadematus*, another spider species that hunts by making webs, was  $0.214 \pm 0.023$  ng/µL. The total RNA amount of *A. pulverulenta*, a spider species that hunts without making a web, was  $0.084 \pm 0.009$  ng/µL and the total RNA amount of *D. lapidosus*, another spider species that hunts without making a web, was  $0.107 \pm 0.008$ .

**Figure 1.** Total protein and RNA amounts of spider species

RNA analysis is important in determining the responses of organisms to different environmental conditions at the molecular level. RNA analysis provides preliminary information in determining the properties of proteins produced in organisms with different living conditions.

Saravanan, (2006) gave information about the structure and properties of spider web in his study. According to this information, spider web consists of 80% water, amino acids, glycoproteins, fats, salts and molecular weight compounds. The remaining 20% consists of filaments. The amount of glycoproteins in the filaments is determined by gene expression. This information shows that high amino acid and high protein synthesis is required to produce a network. The information obtained as a result of our study is in parallel with these data.

İde et al., (2011) determined the characteristic features of spider webs in their study. In this study, it was revealed that spider webs are of different types such as hiding, feeding, resting, protecting eggs and hunting. In this study, *A. diadematus* spider was used to make webs for hunting and total protein content was determined. The determination of total protein is in parallel with our study.

In this study, in order to obtain preliminary information on the transcriptional and translational expression and gene and protein size of web-building and non-web-building spider species with different ecological niches and different hunting strategies, total RNA and total protein levels were compared and similarities or differences between different species at the molecular level were determined by biochemical analysis. For this purpose, two spider species with ecological niches were selected.

As a result of the study, it was observed that the total protein ratio of web building spider species was higher than that of spider species that hunted without building webs. In addition, it was determined that the total mRNA ratio was higher in the web building spider species than the others. As a result, it was concluded that spider species that hunt by making webs do more transcription and translation than spider species that hunt without making webs. This result reveals that web-building spider species synthesize more proteins and express more genes than non-web-building spider species.

## CONCLUSION

In conclusion, it was observed that spider species with different hunting strategies produced more RNA and protein transcriptionally and translationally than spider species with different hunting strategies. It is known that various factors have an effect on the amount of total RNA and therefore total protein. In this study, it has been demonstrated that when a spider has the capacity to make a web, it performs more transcription in order to produce the web, which has a protein structure, and as a result, it produces more protein.

#### **Abstract**

Potato common scab is one of the most common diseases of potato, worldwide. There are some pesticides available but due to their side effects on human health and other living organisms, there is a need for more sustainable alternative ways. Using antagonistic bacteria may offer an alternative way to harmful pesticides. In this study, we aimed to determine the biological control activity of antagonistic bacteria isolates using the agar diffusion method against *Streptomyces scabiei* (N131). As a result of this study; Kn1c isolate was identified as a *Paenarthrobacter aurescens* by MALDI-TOF MS analysis. It was shown 29 mm inhibition zone and 9.77 inhibition zone index. In future prospects, *Paenarthrobacter aurescens* may be proposed as a potential biological agent against potato common scab.

**Keywords:** Potato, common scab, antagonism, MALDI-TOF MS

#### **INTRODUCTION**

Potato is one of the most important food sources that fulfill the nutritional needs of the world's population. It is a rich source of protein, carbohydrates and various other vitamins and minerals. Pests and diseases are the key biotic factors that cause huge annual yield losses in potato crop. Among several diseases, Potato common scab, caused by *Streptomyces spp.* is indigenous to all potato growing areas in the world (Loria et al. 2006; Dees & Wanner 2012). A few species of *Streptomyces* can cause potato common scab but *Streptomyces scabiei* is considered to be predominant (Wanner, 2006). The disease has little impact on total potato yield but spoils the appearance, quality, and marketability of the potato tubers (Loria et al. 2006). For management of potato common scab, cultural practices (irrigation during tuber growing stage), crop rotation (Loria et al. 2006; Dees & Wanner 2012), physical, mechanical, organic and biological control methods have been used.

Nowadays, synthetic pesticides have been widely used for to management of pests and diseases. The heavy usage has damaged human health, ecological balance, and animals. For this reason, ecological and biological management methods have become important against chemical control. One of the most important methods is the use of biological control by antagonistic bacteria. Biological control including environmentally friendly applications is one of the most important disease control methods. The advantages of synthetic pesticides include a mix of active ingredients (Bedmutha et al. 2011), low mammalian toxicity and non-persistence in fresh water and soil (Isman 2000). Some studies have reported the antibacterial effect of nonpathogenic *Streptomyces sp.* or other nonpathogenic bacteria against potato common scab (Han et al., 2005; Hiltunen et al., 2009; Meng et al., 2013; Wanner et al., 2014; Arseneault et al., 2015; Chen et al., 2017; Lin et al., 2018; Karagöz et al., 2018; Shuang et al., 2020, Cui et al., 2022).

In this study; we isolated a biocontrol agent from soil. Biological control of obtained candidate isolates was detected by disc diffusion methods. The aim of this study was to evaluate the antibacterial activity of nonpathogenic bacteria obtained from soil against potato common scab disease caused by *Streptomyces spp.*

## MATERIALS AND METHODS

### Pathogenic Bacterial Culture and Inoculum Preparation

Pathogenic *S. scabies* isolates N131 which were previously isolated from scab lesions on potato tubers grown in Niğde province. Pathogenicity of these isolates was confirmed using the pathogenicity test such as Potato slice test and raddish seedling. In previous work, pathogen isolate N131 was characterized by thaxomin production and potato tuber pathogenicity test.

### Isolation of candidate antagonistic bacteria

Surveys for the isolation of antagonistic bacteria were carried out in different districts in Niğde province, Turkey. 200–300 g of rhizosphere soil from serious free PCS-infected area was collected at the potato planting period. All samples taken during the survey studies were individually labeled and placed in transparent polyethylene bags. The samples were kept in ice boxes until they were brought to the laboratory. Antagonistic bacteria were isolated from the healthy potato tuber around. Suspensions with soil samples (10 g) and 90 mL of Nutrient Broth media (NB) were mixed in a shaker incubator at 27°C for 20 min, and diluted to 5 times. The diluted samples (100 µL) were then incubated on King B (KB medium) at 27°C for 48 h. After 48 h, bacteria with different sizes and morphologies appeared on the plates, and were individually isolated from single colonies and purified in KB medium.

### Pathogenicity test of candidate antagonistic bacteria

Isolated antagonistic bacteria was tested by tobacco hypersensitivity (HR) test and potato pectolytic activity test. For the tobacco hypersensitivity (HR) pathogenicity test: the tobacco leaves with the help of a sterile needle, and bacterial solutions were injected between the veins of the tobacco leaf (*Nicotiana tabacum*) with a sterile injector. Sterile pure water was used as negative control. The isolates that produced necrosis were evaluated as HR positive (+), and those that did not form were evaluated as HR negative (-). For the potato pectolytic activity pathogenicity test; disease free potato tubers were sliced approximately 5 mm and placed in petri dishes. Then all isolates were inoculated on the potato slices. It was used the *Pectobacterium carotovorum* pv. *carotovorum* as a positive control and sterile water used as negative control. Petri dishes was incubated at ±26°C. After 24-72 hours, they were checked whether there was softening and they were evaluated as positive in case of softening.

### Evaluation *in vitro* antibacterial activity of antagonistic bacteria

*In vitro* antibacterial activity of the candidate antagonistic bacteria was evaluated by disc diffusion methods with the determination of inhibition zones. Pathogen strain was grown on Yeast Malt Extract Agar (YME) for one week at 28 ± 2 °C. Then one loop spore was transferred to YME broth and incubated in same conditions at 200 rpm. After the incubation period, bacterial cells were harvested by centrifugation at 8000 x g for 10 min and were rinsed twice with sterile distilled water (sdH<sub>2</sub>O). Bacterial density was adjusted to ~ 1 X 10<sup>6</sup> cfu ml<sup>-1</sup> with serial dilutions. Candidate antagonistic strains were grown on Nutrient Agar (NA) medium for 24 h, at 26 ± 2 °C. Single colony was transferred to Nutrient Broth (NB) and incubated in same conditions at 200 rpm. Then bacteria were harvested by centrifugation at 5000 x g for 5 min and were rinsed twice with sdH<sub>2</sub>O. Bacterial density was adjusted to OD<sub>600</sub> = 0.5 with sdH<sub>2</sub>O. Inhibitory effects of the candidate antagonistic strains were defined with agar disc diffusion method (Kimura *et al.*, 1998). Briefly, 50 µl of pathogen solution was pipetted on YME agar and was spread with sterile swab. Then 10 µl of candidate bacteria solution was pipetted on the 6 mm sterile disc, placed on center of the pathogen inoculated YME. The plates were incubated for one week at 28 ± 2 °C. After the incubation period, inhibition zones around the discs were recorded. The antagonistic activity of the bacteria was calculated by subtracting the colony diameter from the inhibition zone diameter. The assays were independently repeated three times.

### Identification of antagonistic bacteria

All candidate isolates were diagnosed firstly with MALDI-TOF MS according to the method described by Duman and Soylu (2019). The bacterial mass taken from the pure colonies of the isolates and obtained from the colonies developed for 24–36 h on Tryptic Soy Agar (TSA) medium was added to Eppendorf tubes with 300 µl of sterile distilled water. Tubes were agitated in the vortex, and the bacteria suspension was obtained. After adding 900 µl of pure ethanol (Merck, Darmstadt, Germany) into the tubes, the mixture was centrifuged at 13.000 rpm for 2 min. Supernatant discharged and the remaining pellet was centrifuged for 1 min at 13.000 rpm again. If ethanol residue was observed, the remaining ethanol was carefully removed with a pipette, and

the resulting pellet was allowed to dry at room temperature (about 5 min). 30 µl of 70% formic acid (Merck, Darmstadt, Germany) was added into the tube containing dry pellet and vortexed again at 13.000 rpm for 1 min, then 30 µl of acetonitrile was added, and the mixture was vortexed at 13.000 rpm for 1 min. Finally, 1 µl of the supernatant was added to the target plate in two replicates, followed by drying at room temperature (approximately 3–5 min), and addition of 1 µl HCCA Matrix on each sample point ( $\alpha$ -Cyano-4-hydroxycinnamic acid) and drying. Brukers Bacterial Test Standard (Bruker Daltonics GmbH, Bremen, Germany) was used as Mass calibration standard. Samples were loaded onto the MALDI-TOF MS (Microflex LT; Bruker Daltonics GmbH, Bremen, Germany) with the Flex Control Software (Bruker Daltonics GmbH, Bremen, Germany). Each spectrum was obtained with 500 laser beams with the minimum laser power required for ionization of samples in automatic mode. The spectrum was analyzed at m/z (mass/charge) ratio in the range of 2–20 kDa. BIOTYPER™ 1.1 software (Bruker Daltonics GmbH, Bremen, Germany) was used as microorganism library. Four isolates, showing highly antagonistic effects in vitro, were selected for in vivo tests. Molecular identification of these four isolates were also performed using universal primers 27F and 1492R. Genomic DNA was extracted using the genomic DNA Purification Kit (GeneJET; Thermo Scientific Fermentas, Vilnius, Lithuania) according to the manufacturer's instructions. PCR assays were performed using universal primers 27F 5'-AGA GTT TGATCMTGG CTC AG-3' and 1492R 5' TAC GGY TAC CTT GTT ACG ACTT designed by Fredriksson et al. (2013) which produced a fragment of 1494 bp. The sequences were compared with those available in the NCBI Blast analysis ([http:// www. ncbi. nlm. nih. gov/](http://www.ncbi.nlm.nih.gov/)). In vitro, antibacterial activity was estimated using formula:

$$(ZD-DD)/ID \times 100$$

ZD: Inhibition zone diameter

DD: Disc diameter

#### Statistical analysis

All data were replicated three times and analysis of variance (ANOVA) was done by using SPSS software. The mean values were compared with Duncan multiple range test at a probability of 5% ( $P < 0.05$ ).

## RESULTS and DISCUSSION

A total of 50 bacterial isolates obtained from soil samples of potato rhizosphere soil showed antagonistic activity to *S. scabiei* (Table 1). Among these isolates, 15 isolates showed pathogenic character according to tobacco hypersensitivity (HR) and potato pectolytic activity pathogenicity test. Totally 27 isolates showed antibacterial effect. Among these isolates, Kn1c isolate showed a higher antibacterial effect as compared with the other isolates. Kn1c isolate exhibited the strongest antagonistic activity towards the growth of *S. scabiei* and the growth inhibition zone 29 mm and 9,77 in inhibition zone index (Figure 1). According to the MALDI-TOF MS diagnostic results of Kn1c isolates, it was found *Paenarthrobacter aureus* (Table 1).

**Figure 1.** Antibacterial effect of Kn1c against *Streptomyces scabiei*

Several studies have used biocontrol agents as; *Pseudomonas* spp. and *Bacillus* spp. to management of the potato common scab. Han et al. 2005, isolated the antagonistic bacteria and *Streptomyces scabiei* isolate from soil and identified the beneficial bacteria as a *Bacillus* sp. It was found decreasing the infection rate from 75 to 35% using by pot assay. Meng et al. 2012, isolated the antagonistic bacteria potato common scab suppressive soil, was identified as *Bacillus amyloliquefaciens* (BAC03). Antagonistic activity of BAC03 was displayed against *Streptomyces* spp. According to pot assay, BAC03 reduced common scab severity and potentially increased the growth of potato plants. Karagöz et al. 2018, detected the biological control effect of 1048 bacterial isolates from former studies were tested against *S. scabiei* in-vitro and 22 out of these strains were found to be effective. Among this isolates, four strains (KBA-10, K-19B, TV-91C and RK-92) showed highest antibacterial effect and those were chosen for field trials. It was identified as *Bacillus zhangzhouensis* by 16S general primers pairs by PCR analysis. According to field assay; KBA-10 was found most effective biocontrol agent for reducing potato scab disease and enhancing crop yield. Cui at al. 2022, were isolates 75 endophytic bacteria from the healthy potato tubers and strain 3-5 was selected as an optimal antagonistic bacterium against *Streptomyces griseoplanus* (*Streptacidiphilus griseoplanus*) using by the dual-culture method. Strain 3-5 was identified as *Bacillus amyloliquefaciens* based on its morphological characteristics and 16S rDNA general genes. It was found successful in controlling potato scab with a  $38.90 \pm 3.2140\%$  by field assay.

## CONCLUSION

Potato common scab is an important soil-borne disease, which occurs in most potato growing areas of the world. In this study, we evaluated the antibacterial activity of antagonist bacteria against potato common scab disease.

In this study, we used the *Streptomyces scabiei* as a pathogenic isolate. Then antagonistic bacterial samples were isolated from rhizosphere of healthy potato tubers. A totally 27 isolates showed antagonistic effect against the pathogen by disc diffusion test.

According to petri assay, Kn1c isolate showed highest inhibition zone and index then other isolates, 29 mm and 9,77 respectively.

Kn1c isolate was identified as *Paenarthrobacter aureescens* by MALDI-TOF MS analysis.

As a result of this study, *Paenarthrobacter aureescens* has highest antibacterial effect on potato common scab. In summary, the tested antagonistic bacteria isolate especially *Paenarthrobacter aureescens* seem to be promising tools for the control of potato common scab. Future works need to be confirmed these findings through the application of the studied isolates in field experiments. In addition, future experiments are needed to test genomic characterization and biological control mechanism as well.

#### ACKNOWLEDGEMENTS

This study was supported by TÜBİTAK 1002 project (121O224). The current research was produced by the Doctoral Thesis of Nida ÜNLÜ that was carried out at Niğde Ömer Halisdemir University Niğde, Turkey.

### Abstract

Cellulose is an indispensable raw material and also the world demand for cellulose has been increasing day by day. Apart from the basic usage areas of cellulose in paper, and cardboard, in the petrochemical and construction sector, in the paint and coating industry. it is an essential raw material used in food, medicine, cosmetics, the textile industry, and many industrial categories.

Algae, especially green algae, are good sources of cellulose and developments in the paper pulp industry have made Macroalgae practical alternatives to the use of trees (De Poli et al., 1994; You, 2008).

In this research, the usage of *Ulva lactuca* in cellulose production was determined. The study results showed that the content of raw cellulose was 22.21 grams per 100 gr dry weight of *Ulva lactuca*. And, the amounts of  $\alpha$  (Alpha) and  $\beta$  (Beta) cellulose fractions were 6.58 and 23.35 grams per 100 gr dry weight of *Ulva lactuca*. From the study result, it was concluded that it is effective and favorable to use high  $\alpha$ (Alpha) cellulose containing *Ulva lactuca* in paper production and high  $\beta$  (Beta) cellulose containing *U. lactuca* in bioplastic production.

**Keywords:** *Ulva*, raw cellulose,  $\alpha$  (Alpha) cellulose,  $\beta$  (Beta) cellulose, paper production, bioplastic production.

### 1. INTRODUCTION

Cellulose is the most familiar linear polymer in the world, simply formed by glycosidics in  $\beta$ -1 of D-glucopyranose (Staudinger, 1932; Gilbert and Kadla, 1998). Cellulose is an indispensable raw material and also the world demand for cellulose has been increasing day by day. Apart from the basic usage areas such as Cellulose, paper, and cardboard, in the petrochemical and construction sector, in the paint and coating industry. In addition, it is an essential raw material used in food, medicine, cosmetics, the textile industry, and many industrial categories.

Cellulose is found in the cell wall structure of plant materials (wood, linen, bamboo, cotton). More extra than 90% of cotton threads, about 50% of wood, 30% of straw is cellulose. Cellulose, which is processed into commodities, is most commonly obtained from plants. Whereas, lignin and hemicellulose must be separated from cellulose for the obtained cellulose to be used in industry. On the other hand, this process contaminates the environment. It is complex, difficult, and expensive. In addition, it creates a reduction in the world forest's existence, habitats. Cutting down forests affects air pollution, greenhouse effect, and homelessness of the creatures living in the forest. It is an important point that trees clean the carbon dioxide produced by about 1000 people in 1 day, prevent landslides and create living spaces for living things. End of these reasons, different cellulose sources have been investigated in recent years.

The most important circulation area of algae, where 70% is distributed, is water. They are the major fundamental generators of organic carbon composites in these environments. In addition, they can live in ice-covered areas, in spring waters with a temperature of 70 °C or higher, in saltwater habitats, in lakes and seas 100 m below the surface, or under low light intensity and high pressure.

Algae are structurally classified into two wide categories: prokaryotic (microalgae) and eukaryotic (macroalgae). Microalgae are identified as "Blue-green algae (Cyanophyta)". On the other hand, Macroalgae are classified as Brown algae (Phaeophyta), Red algae (Rhodophyta), Green algae

(Chlorophyta), Diatoms (Chrysophyta), and Flagellata algae according to their flagella or pigmentation.

Algae are utilized as nutrients due to the presence of vitamins, minerals, proteins, and carbohydrates; in cosmetics, leather, textile, paint, paper industry; in medicine (in the treatment of constipation, as a blood coagulant, in antibiotics); as animal feed and fertilizer. Moreover, it is used in the beer industry, heat insulation, cleaning industry, sugar refinery, glass factories, waste treatment, and many other spheres.

The aim of this study was to extract cellulose from a green seaweed *Ulva lactuca* with its fractions of  $\alpha$  (Alpha) and  $\beta$  (Beta) cellulose fractions

## **MATERIALS AND METHOD**

### **Supply of *Ulva* Samples**

During this study, green seaweed *Ulva lactuca* samples obtained from the Macroalgae Cultures in the Algae Culture Laboratories at Ege University, Fisheries Faculty, in Bornova and Urla Research Center where they were cultivated in Guillard's F/2 culture medium (Guillard and Ryther 1962, Guillard 1975). *Ulva lactuca* cultures are originally supplied from the natural stocks located at Bostanlı Harbor (İzmir Bay, Türkiye). For this experiment, *Ulva lactuca* cultures were kept in 1 L glass jars enriched with Guillard's F/2 Medium ( $10 \text{ ml.L}^{-1}$ ) and continuous aeration and light conditions were applied.

### **Preparation of *Ulva* Samples for Cellulose Production**

The whole experimental process was applied below sterile conditions and following laboratory conformities. Cellulose was isolated applying the method Mihranian et al. (2004) and (2007) Cellulose was acquired by extraction of dried 100 g of algae powder with Methanol (MeOH,) and it was saved at room temperature using a meseration method over eight days. At the end of the processing, the lingering algae powder was kept in 1 L acetate buffer buffer including 36 g NaClO (commercial bleach) for bleaching at 60 °C for 3 hours. The bleached algae mass was washed with water until pH 7 and filtered. The washed algae mass was incubated in 600 ml NaOH (0.5 M) solution at 60 °C overnight. The alkali-treated algae mass was washed with water to neutralize, filtered, and was dried at room temperature. The dried commodity was heated to boiling again in 200 ml of hydrochloric acid and the resulting slurry was kept at 30 °C overnight, then washed with water to remove excess acid, filtered; and dried at room temperature to obtain cellulose. The amount of cellulose was calculated by weighing (subtracting the final weight from 100 g).

### **Separation of Cellulose Into Its Components (Alpha- and Beta-Cellulose)**

Alpha and beta fractions were acquired from celluloses utilizing the method inscribed by Whistler (1963). 1 gram of dried cellulose was retained in 30 ml of alkali (17.5% NaOH) solution for 2 hours at 20 °C and shaken every 15 minutes. The resulting slurry was centrifuged at 8000 rpm for 15 minutes. At the last step, the amounts of the  $\beta$  (Beta) fraction from the upper part (supernatant) and the  $\alpha$  (Alpha) fraction from the lower part (residue) were calculated from the tubes extracted from the centrifuge.

## RESULTS

**Table 1. Cellulose Amounts Obtained From *Ulva lactuca***

	<i>Ulva lactuca</i>
Cellulose (g)	22.21g

It was specified as clearly on the table that the amount of isolated cellulose was 22.21 grams from *Ulva lactuca* (Table 1),.

**Table 2. Amounts of  $\alpha$ (Alpha) and  $\beta$ (Beta) Cellulose Obtained From *Ulva lactuca***

	<i>Ulva lactuca</i>
$\alpha$ (Alfa) Selüloz	6.583g
$\beta$ (Beta) selüloz	23.353g

The amounts of  $\alpha$  (Alpha) and  $\beta$  (Beta) cellulose fractions were 6.58 and 23.35 grams per 100 gr dry weight of *Ulva lactuca*.

## DISCUSSION AND SUGGESSTIONS

In this study, the possibility usage of *Ulva lactuca* utilized in cellulose production was determined. The study results showed that the content of raw cellulose was 22.21 grams per 100 gr dry weight of *Ulva lactuca*. And, the amounts of  $\alpha$  (Alpha) and  $\beta$  (Beta) cellulose fractions were 6.58 and 23.35 grams per 100 gr dry weight of *Ulva lactuca*. From the study result, it was concluded that it is effective and favorable to use high  $\alpha$ (Alpha) cellulose containing *Ulva lactuca* in paper production and high  $\beta$  (Beta) cellulose contenting *U. lactuca* in bioplastic production.

It is the most important idea that diverse types of algae can be tested in future studies. The use of algae that grows naturally in the waters Türkiye can be extended in different areas.

**CONFLICT OF INTEREST:** The authors have declared no conflict of interest.

#### Abstract

Due to continued use of fossil fuels is not sustainable as they are a finite resource and their combustion lead to environmental problems, the recent investigations started to focus on more renewable energy resources. As an alternative energy resource Biodiesel is an environmentally friendly and renewable fuel source obtained from vegetable oils and used in diesel motors. Since some of terrestrial plants, such as soybean, canola, corn, coconut and palm tree oils used in food purposes and they require huge areas to grow, in recent years studies on microalgae as renewable fuel resources gained more attention due to their surprising ability to grow in unused areas.

Microalgal lipid production is very important for the aquatic ecosystem. Algae can synthesize methabolites such as fatty acids, sterols, carotenoids and lipids that have similar composition found also in the terrestrial plants. The lipids produced by algae and stored as unsaturated fatty acids are the main energy resources of the aquatic invertebrate and fish species. Additionally, these lipids are considered as potential diesel fuel resources.

Aim of this study was to summarized biomass yield and lipid production of various microalgal species of cultured in phototrophic systems.

**Key Words:** Microalgae, energy, biofuel, biodiesel, global warming.

#### 1. Introduction

Biodiesel is a renewable energy sources that is produced from oil crops such as plants, animals and microalgae. Biodiesel is known as fatty acid methyl esters originating from vegetable oils and animal fats (Miao and Wu, 2006). In biodiesel production, triglycerides are reacted with methanol by a catalyst. This process is known as transesterification. Biodiesel can be produced from any material that contains fatty acids which can be linked to other molecules or present as free fatty acids. Hence various oil such as animal fats, vegetable and microalgal oils can be used for biodiesel production.

Like plants, microalgae use sunlight to produce oils however their production is more efficient than crop plants (Demirbaş and Demirbaş, 2010; Sheehan et al., 1998). Oil productivity of many microalgae is higher than the best oil producing crops (Ahmad et al., 2011). Microalgae have been suggested as very good candidates for biodiesel production, because they have some advantages such as higher photosynthetic efficiency, higher biomass production and faster growth compared to other energy crops (Miao and Wu, 2006). Additionally, it provides advantage for usage of unfertile lands, inefficient for agriculture, for biodiesel production instead of using productive lands for food production (Sheehan et al., 1998).

#### 2. Biodiesel From Microalgae

Algae are photosynthetic organisms that found in marine and freshwater environments. They utilize sunlight to convert chemical energy. This chemical energy is used to drive chemical reactions such as the formation of sugars or the fixation of nitrogen into amino acids, the building blocks for protein synthesis. Microalgae are sunlight-driven cell factories that convert carbondioxide to potential biofuels, foods and fine bioactive chemicals (Chisti, 2007). The inefficiency and unsustainability of

the use of food crops as a biodiesel source have increased interest in usage of microalgae species as a renewable energy source (Miao and Wu, 2006).

### **2.1.Advantages of Biodiesel Production from Microalgae**

Microalgae contain lipids and fatty acids as membrane components, storage products, metabolites and resources of energy. Algal strains, diatoms and cyanobacteria have been found to contain relatively high levels of lipids. The most off microalgae can produce and accumulate hydrocarbons and oil content that can exceed 80% of dry weight (Table 1). Oil productivity, that is the mass of oil production per volume per day depends on algal growth rate and oil content of the algal biomass (Chisti, 2008).

Microalgae have several attractive characteristics for biodiesel production: Doubling time is shorter than other biomass materials such as trees, animals etc. and microalgae have higher growth rates. Higher yield and oil productivity-lower cost. Costs related with their harvesting, transportation of microalgae are lower than other biomass materials. Microalgae are biodegradable and they can be chemically treated easily. Their cultivation is not complex; algae can grow practically in every place where there is enough sunshine.

Microalgae are capable of fixing CO<sub>2</sub> in the atmosphere, thus facilitating the reduction of increasing atmospheric CO<sub>2</sub> levels, which are now considered global warming. Microalgae do not compete for land with crops used for food production. The cultivation of microalgae does not require a large area of land compared to other plant sources. In addition, they do not directly affect the human food supply chain, eliminating the food versus fuel dispute.

Microalgae produce valuable co-products or byproducts such as biopolymers, proteins, carbohydrates and residual biomass, which may be used as feed or fertilizer. Microalgae are considered to be an efficient biological system for harvesting solar energy to use in the production of organic compounds (Ahmad et al., 2011; Chisti, 2008). Agricultural oil crops, such as soybean oil and oil palm, are widely used to produce biodiesel. However their oil content is less compared with microalgae shown in Table 2 (Chisti, 2007).

This is nearly 61% of all agricultural land in U.S. based on these biomass calculations, biodiesel replacement petroleum diesel is not realistic and reasonable. On the other hand microalgae oils have potential because of their growth rate. Their doubling times are 24 h and during exponential phase this can be as short as 3.5 h. In addition thier oil levels reach up to %20-50. Additionally, it is worthwhile to compare other bioenergy sources such as bioethanol. Bioethanol has only 64% of energy content of biodiesel. Hence,  $0.53 \times 10^9 \text{ m}^3$  biodiesel requirements substitute with bioethanol,  $828 \times 10^6 \text{ m}^3$  bioethanol will be needed.

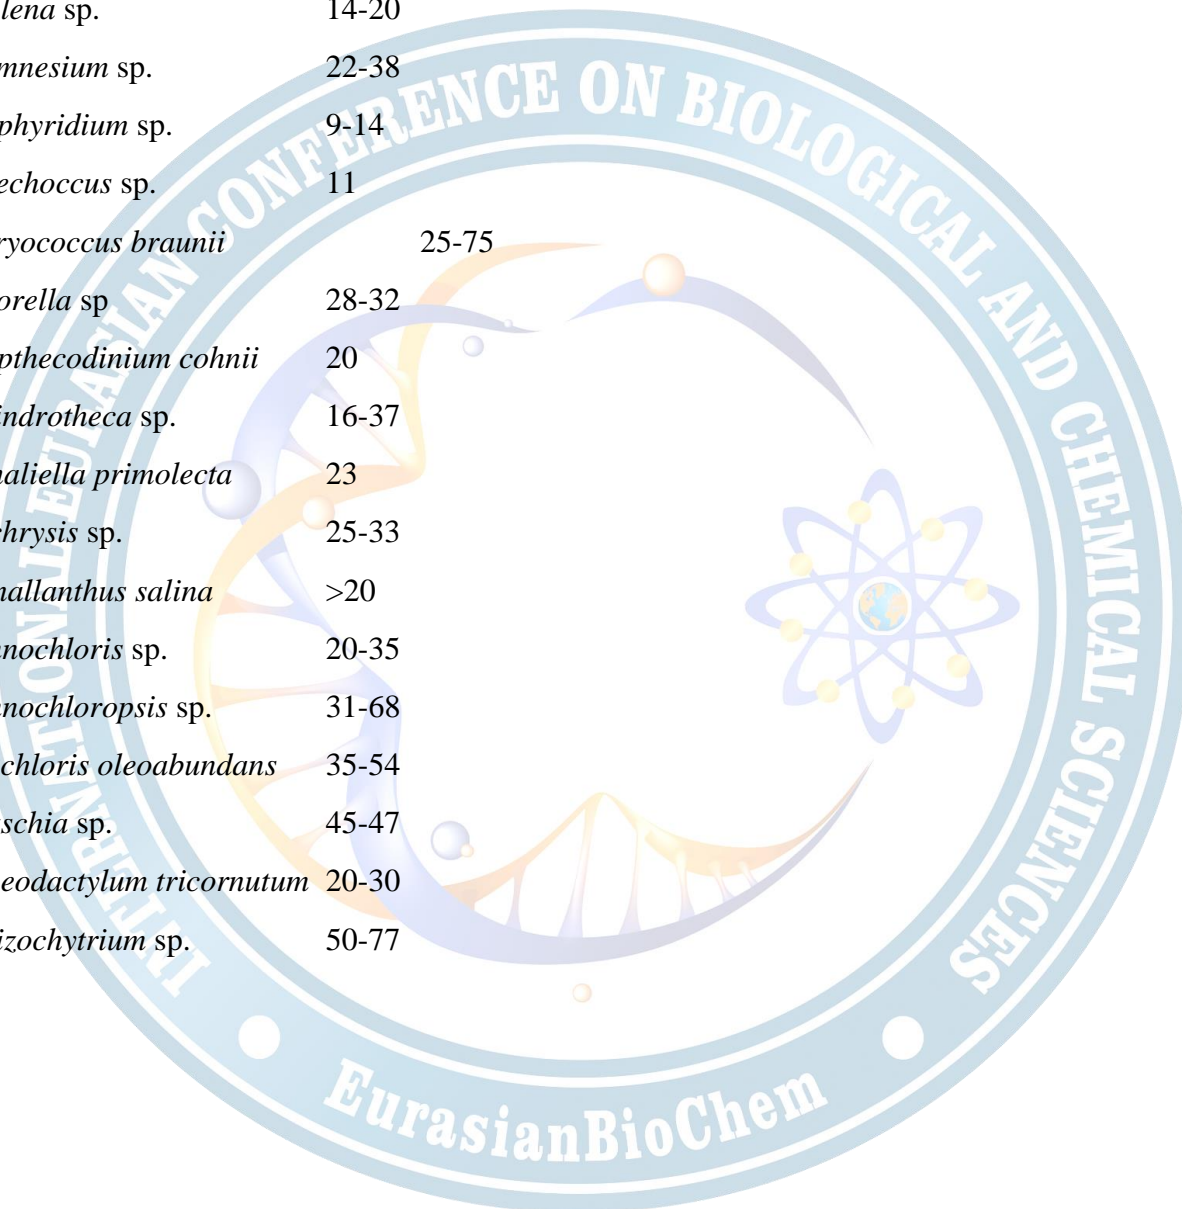

### **2.2.Algae Production Systems For Biodiesel**

Photosynthetic growth requires light, carbon dioxide, water and inorganic salts. Also temperature must remain generally within 20-30°C (Chisti, 2008). Several methods can be used to grow large scale of phototrophic algae. These systems include outdoor systems such as open ponds and tanks where the light source is sunlight and closed systems such as photobioreactors (Andersen, 2007).

Growth medium must provide the inorganic elements. Essential elements include nitrogen (N), phosphorus (P), iron and in some cases silicon especially diatoms (Chisti, 2008). Although sunlight is used as a light source in outdoor systems, electric lights are used for illumination in closed systems. Photobioreactors are defined as closed systems and these systems provide the control and optimization of culture parameters. Also photobioreactors prevent contamination. But in outdoor systems, algal culture can be contaminated by the other algal species or microorganisms. Therefore outdoor systems are only used for algae that grow in extreme conditions such as pH, temperature (Del Campo et al.,2007).

**Table 1: Oil content of some microalgae (Chisti, 2007 and 2008)**

Strain	% Oil content (Dry weight)
<i>Scenedesmus</i> sp.	12-40
<i>Chlamydomonas</i> sp.	21
<i>Chorella</i> sp.	14-22

Oil palm	5950	45	24
<sup>b</sup> Microalgae	136,900	2	1.1
<sup>c</sup> Microalgae	58,700	4.5	2.5

<sup>a</sup> For meeting 50% of all transport fuel needs of the United States.

<sup>b</sup> 70% oil (by wt) in biomass.

<sup>c</sup> 30% oil (by wt) in biomass.

### 3. Conclusion

Biodiesel produced from microalgae is a new sustainable energy source substituted for petroleum diesel. Microalgal biodiesel is technically feasible because of the possibility of using the same engines and equipments used for petroleum diesel. Large scale microalgal production is needed for microalgal biodiesel to be used instead of petroleum diesel. These large amount of algal biomass could be cultivated in photobioreactors but a favorable assessment of the economics of production is necessary to establish.

Cultivation of microalgal biomass in open ponds, especially in sunny and temperate region, could be very economic. Additionally, open ponds in hectares of area, could remove excess CO<sub>2</sub> in atmosphere with photosynthesis. This could be not only a solution for renewable energy production but also a solution for CO<sub>2</sub> problem causing global warming. Microalgae with their high doubling time and photosynthetic activity, could be the only quick solution for solving global warming problem in short term.

### Abstract

Seaweeds are a lot of bio-compounds and others chemical sources that can be used in industry, and in the last years came gained attention, mainly in areas of food, drug, agriculture, aquaculture, bio-energy, and degradable film and others products.

They can be found in the oceans and fresh water as well that have light access. Macro-algae are eukaryotic, macroscopic multicellular algae commonly know by seaweeds. They need to be fixed on solids subtracts to live, can be rock, ship hulls, immersed woods, even pipes because they benthonic habits. They don't have a complexes structure at all, owing thallus, lamina, kelp, holdfast and frond sorus, thus morphologically differentiating it from the typical terrestrial plant, consisting of complex tissue and organ organization. (Milledge et al., 2014).

Seaweeds are divided in three groups based on their most important pigments, are they: Chlorophyta (green algae) with chlorophylls a and b), Ochrophyta (or its previous name Phaeophyta) (brown algae) with chlorophylls a and c) and Rhodophyta (red algae) with chlorophylls a and d). Green algae can absorb a huge amount of light energy, while red and brown algae cannot as they live in deeper waters where there is insufficient sunlight. Brown algae account for approximately 59% of the total macro-algae cultivated in the world, followed by red algae at 40% and green algae at less than 1% (Christaki et al., 2012).

The purpose of this review article is to show some products prepared from micro- and macro-algae, such as fertilizers, drugs, drugs, pigments and biofuels.

**Keywords:** Seaweeds, Bio-fuel, Bio-fertilizer, Pigments, Pigments, Drugs

### Seaweed as Bio-Energy

There is a big vantage in use of seaweeds to produce energy, the better vantages is your rapid growth rate and high concentrations of chemical compounds as lipids and oils. Thus, macro-algae are one of the best feed-stocks useful to produce a lot of products, like biodiesel (Nigam, 2011). And the left residue after post-lipid extraction process called non-ligno-cellulosic waste, a good material to produce (Barskov, 2019).

In addition of biodiesel and bio-coal, the seaweeds can be used for produce others form of bio-fuels, for example: bio-ethanol, hydrogen and bio-gas and a lot of others types of hydrocarbons besides of variants forms depending on the nature of the feed-stocks (Fogaça, 2013).

Algae content high oil amounts, and in some cases this can be as high as 80% oil per dry weight. They can produce at least 30 times more energy per hectare than land crops. Under optimal conditions, it can be produced 137,000 liters of oil per hectare per year (Fogaça, 2013).

Bio-diesel and other compounds have many environmental benefits such as to be nontoxic, and biodegradable. They are mono alkyl esters of long chain fatty acids that can be produced from acyl-glycerol (usually triglyceride) in vegetable oils or animal fats. (Cheng L, 2012).

Algae can be produced successfully with applications of some modified conditions to produce different quality compounds, as quantities as well. Different species growing in different conditions can offer different levels of carbohydrate, lipid and protein. The plasticity of their biochemical characteristics makes possible to use algae biomass as biogas, bio-hydrogen, bio-diesel and bio-ethanol (Jones, 2012).

After drying algae, they are placed in a reactor, which performs the extraction of the oil that will be used in the manufacture of the fuel and the transformation of this oil into biodiesel, through chemical reactions. Usually the result is around 10% to 20% of the total raw material used. In order to produce one liter of biodiesel, it takes about approximately 2 kg of algae. The remainder can be used to produce other by-products such as fertilizers, bio-coal, bio-ethanol and bio-gas (Smith, 2016; Adam, 2008; Adam, 2012).

This phenomenon happens because seaweed has a lot of different chemical characteristics with different classes of molecules, so an algae waste of bio-diesel can be used to produce other types of sub-products, like bio-kerosene (Castilhos, 2008).

A lot of elements can be found in water residue of extraction process, like potassium, phosphorous, calcium, magnesium and others. So this residue may be recovered and used as fertilizers for agriculture activities (Smith, 2016).

Bio-ethanol needs to pass through biotechnological procedures to cleave the sugar by fermentation using microorganisms. Some class of sugar and other carbohydrates will not be able to be cleaved by the microorganisms, so it will need primarily to be processed with altered temperature, pH, enzymes hydrolyses to turn these compounds able to fermentation phases. Distilled bio-ethanol mixed with petrol (gasoline) in proportions of 5% (v/v) was able to be used in vehicles without alterations (The European Parliament and the Council of the European Union, 2003).

The general approach involves extraction of algal oil from dried algae followed by transesterification of the oil to biodiesel using an alcohol in the presence of a catalyst. Algal biodiesel production is the result of the transesterification process, a process of converting vegetable oils into biodiesel. In the transesterification process, the triglycerides present in the oil are transformed into smaller fatty acid ester (biodiesel) molecules from a trans-esterifying agent (primary alcohol) and a catalyst (base or acid) (Fogoça, 2014).

Algal oil transesterification is usually done with ethanol and sodium ethanoate to serve as a catalyst. Thus, the catalyst assists in the reaction with algal oil (triglycerides) to produce bio-diesel and glycerol. The final reaction products are therefore biodiesel, sodium ethanoate and glycerol. The end products of the transesterification reaction are mixed ether and salt water and after some time, all this mixture will separate into two heterogeneous phases, with the bottom phase containing a mixture of ether and bio-diesel and glycerol stays at the upper part. Bio-diesel is separated from ether by a vaporizer under a high vacuum. As ether evaporates first, Biodiesel remains and bio-diesel from algae will be ready for use (Fogoça, 2014).

Bio-coal can be produced starting with approximately 80% of seaweed dry biomass. There is a difference between terrestrial plants and seaweeds, the treatment that was used to coal plants is not able to produce seaweed coal, because high water content in seaweeds or algae that hinders the production of coal. The high chlorine, ash and alkali content, low calorific value and high moisture content make macro-algae as an unattractive option for combustion, pyrolysis or gasification. So, some special

treatments before the process, like thermal drying and de-mineralisation of algal biomass prevent the problems (Ross, 2008).

Algal bio-gas production is the area in which it is being most researched mainly through anaerobic processes (Hughes, 2012) or the production of bio-ethanol via fermentation (Horn, 2000).

There are sugars in the algae, which need to be broken down before going through the other production processes, which can go through fermentation processes using microbiological pathways, producing bio-ethanol. Some of these sugars are not directly available for use by microorganisms, so first they need to be transformed into treatments by pH, temperature, biotechnological procedures, among others, for the fermentation step to take place successfully. An example of these sugars is mannose, which cannot be used by most fermenting organisms and become an alcohol called mannitol. It needs to undergo a fermentative oxidation and becomes fructose by the enzyme mannitol dehydrogenase (Horn et al. 2000a).

From this product, ethanol distillate can be mixed with petroleum at a volume ratio of 1:20 without loss of performance for vehicle use (The European Parliament and the Council of the European Union, 2003). Most macro-algae can go through processes that use heat and fermentation, as mentioned earlier (Adam, 2008). Although, the simplest way to produce energy from algae that to use an anaerobic digestion method to produce biogas. And, anaerobic digestion of micro-algae was found to be easier because it needs less processing protocols and low cellulose content, unlike terrestrial plants (Matsui et al., 2006).

Isolated energy beyond macro-algal performance is a major impact on environmental sustainability and fights against climate change. Knowing that more macro-algae are grown their price gets lower when the price of barrels of oil is so high to increase over the years (Hughes, 2012)

### **Seaweed as Fertilizers**

Macro-algae have several bioactive materials and compounds that stimulate microorganisms in agricultural soils. These substances are most commonly used as agricultural bio-stimulators and among them we can highlight substances and products such as microorganisms, trace elements, enzymes, minerals, plant growth regulators, hormones and various other materials. These substances improve soil quality, causing better physiological results of the plant during cultivation. There are some hormones that like algae produce and are similar when not found in terrestrial plants. The use of these phyto-hormones causes a crucial stimulus in the culture medium. Some studies concluded that these substances and derivatives have several benefits for terrestrial plants (Sharma et al., 2014). Some types of polyoligosaccharides readily found in macro-algae extract play an important role in the hormonal signaling pathways in higher plants (Kraan, 2012). Already brown algae are commonly used because they have several bio-stimulants for agriculture (McHugh 2003).

These are contained with a type of phenolic bio-stimulant known as phlorotannin which is subclassed into fuhalols and phlorethols, fucols, fucophloroethols, and eckols. Those are not found in terrestrial plants. A similarity between plants and algae that are found in extreme conditions, whether with pathogen contact or adverse conditions, they produce compounds that are critical to their defense, so they can be used successfully. These also have several benefits for plants, as mentioned before: antioxidant effects, radio-protective, antiviral and antimicrobial activity, in addition to the ability to regulate enzyme-mediated reactions (Li et al., 2011).

Among more by-products obtained from macro-algae processing, we can mention two other groups, which are carotenoids and fatty acids. These two components participate in various biochemical plant pathways as coenzymes, for example. They also influence physiological processes such as respiration and protection of organelles responsible for photosynthesis in higher plants, as well as functioning as

an enzyme in hormone-dependent regulations. There are also very effective against the plant stress caused by attack of possible pathogens. However, for their high commercial value, especially for the pharmaceutical and cosmetics industries, these elements are not commonly used in agriculture (Cazzonelli et al. 2010).

Mineral-rich biomass obtained from bioenergy production from macro-algae is being commonly used by European agriculture. It is believed that the use of these bio-stimulant components can be a big step towards more developed and sustainable agriculture for the future (Dmytryk, 2018).

### **Seaweeds as Cosmetics and Drugs**

There are several compounds extracted from macro-algae that can be used by the cosmetic and pharmaceutical industries for their benefits to human health. One of these is progerin, which treats a protein that functions like a cell and causes cell senescence in human fibroblasts. This protein can accumulate by the years in the skin and is therefore harder to find in younger fibroblasts (Takeuchi and Runger, 2013). One study showed that progerin amounts significantly decreased when a macro-algae extract was tested, even in the smallest amounts. Although, they did not find any effects of macro-algae extract on younger fibroblasts (Verdy et al, 2011).

Antioxidant agents are naturally chosen by the skin, as they are responsible for action against reactive oxygen. As macro-algae, several antioxidant agents included in its biomass composition can highlight laminaran, fucoidan, fucoesterol and alginate, among others. These have been used for cosmetic skin care products (Wang et al., 2013). Despite the benefits of antioxidants to the skin, they can also guarantee the protection of the product itself, causing them to have an excessively long shelf life, as well as preventing lipid oxidation, changes in appearance, texture and odor of the product. Algal extracts can be found in sunscreen products due to their antioxidant agents protect the skin against ultraviolet rays (Shick and Dunlap, 2002).

Asians have a skin bleaching culture, which are the best known in the world (Li et al., 2008). Tyrosinase catalyzes two distinct and significant reactions in melanin synthesis. Tyrosinase and melanosome production is stimulated by skin contact with sunlight. Thus, the use of tyrosinase inhibitors is the most commonly used aesthetic procedure to promote skin whitening. The tan can be lost with the help of this enzyme, as it has the role of catalyzing a pigmentation step, also causing an epithelial flaking, where the pigments are lost (Wang et al., 2013).

The tyrosinase inhibitor has been studied in recent years, thus number of the research on seaweeds is increased extremely. Seaweed has several different types of pigments, one of them is called Fucoxantin, and is capable of absorbing UV-a and UV-b as well as inhibiting the effects of thisorinase and when administered orally the effect was increased more. Thus, fucoxanthin has been found to have generic roles (Thomas and Kim, 2013).

Polysaccharides are also widely used in cosmetics, in different ways depending on their features and effects. Since seaweeds composition rich in polysaccharide, they become an excellent raw material for working their extracts in the cosmetic industry. Among the most common polysaccharides found in macro-algae, we can highlight the fucoidans originated from brown algae, carrageenans from red algae and ulvans from some green algae. For example, seaweed polysaccharides act as rheology modifiers, suspending agents, hair conditioners, and wound-healing agents, and can also moisturize, hydrate, emulsify, and emolliate (Goddard and Gruber, 1999).

Other hydroxyl acid compounds have also often been used in the cosmetic industry. These can already be found in both the animal and plant species, although their concentrations are relatively low and their price is very high. However, the polysaccharides found in seaweed are already abundant and have lower prices, thus being great substitutes (Wang et al., 2013).

There are a lot of chemicals that are added in cosmetics so you can control their physical properties such as viscosity, transparency, texture, color and so on. One such substance is alginic acid or alginate, which is a type of polysaccharide extracted primarily from brown algae that is used as emulsifiers, stabilizers and gelatinizers in the cosmetics industry as well as in the food industry.

Other polysaccharides also extracted from algae, such as carrageenans and agar-agar, have also alginate-like characteristics and can be used for the same purposes as hydrocolloids and stabilizers. They are applied in various cosmetic products as well (Sachan et al., 2009; Priyadarshani and Rath, 2012).

The way these compounds work is with polyvalent atomic interactions. When a polyvalent cation causes an interpolysaccharide binding, a junction zone occurs in the cross-linking sites. The concentration of these polyvalent interactions is directly proportional to the viscosity of liquids and may, to some degree, make the gelatinous solution characteristic of cosmetic product gels (Goddard, 1999).

Brown algae have several other compounds that have anti-inflammatory, anti-tumor and anti-diabetic, neuroprotective properties and are used in bone treatments. One such compound that known as chloroglucinol (Thomas and Kim, 2013). Another component of cosmetic and pharmaceutical interest is metalloproteinases, which are proteolytic enzymes and they have the ability to digest extracellular materials as well as collagen and proteoglycans, fibronectin and laminin (Bodea et al., 1999).

It is estimated that about \$ 170 billion is moved to seaweed cosmetic industry annually according to the French-based company - Eurostaf (Arora et al., 2012).

### **Seaweeds as Pigments**

Algae are composed of several types of pigments in their composition, among which we can mention phycobiliproteins, carotenoids and chlorophylls, which depending on the type of algae may vary among their types. For blue algae is commonly found type "a" chlorophylls, for green algae the chlorophyll types are "a" and "b", for brown algae chlorophyll types are "a" and "c" and for red algae chlorophyll types are "a" and "d". These are very important for the photosynthesis of algae, besides promoting defenses to the organism, preventing them from damage against solar radiation (Robert, 2005).

These cellular components of algae have also shown other properties such as anti-mutagenic and anti-genotoxic activities, besides being excellent antioxidants, acting against free radicals. Depending not only on the algae group, but also on the species, we can find different types of pigments associated with different effects (Wright et al, 1997).

Among the seaweed pigments, astaxanthin is the most powerful pigment as antioxidant agent. It is stronger than vitamin C and E or any other carotenoid, being an excellent antioxidant against free radicals, preserving the integrity of proteins, lymphocytes and excipient lipids against enzymatic catalase and oxidation (Pan et al., 2012). Application of astaxanthin, either orally or topically have dual benefits, such as suppression of skin pigmentation and inhibition of melanin exposure (Tominaga et al., 2012).

A fucoxanthin, another carotenoid, is able to reduce or cause oxidative stress on the skin caused by German ultraviolet radiation to be a natural term for helping to burn fat.

$\beta$ -carotene is pre-cursor of vitamin A, as well as other activities such as strong antioxidant against free radicals and activities anti-cancer agent in the gastrointestinal tract, anti-arthritis and anti-aging agent.  $\beta$ -carotene is also one of the most easily found carotenes in most foods addition to the algal species (Prasanna et al., 2007).

Lutein is also a very common carotenoid to be found in foods similar to  $\beta$ -carotene. It has the power to protect the skin from ultraviolet rays and is commonly administered along with natural antioxidants and immunostimulants. Previous studies verified the same beneficial activities in lutein against coronary, acute and chronological symptoms. This carotenoid acts mainly on vision, being effective against the development of cataract and atherosclerosis, besides being an immunostimulant prevents bacterial infection and delays aging (Yaakob et al., 2011).

#### Abstract

$\beta$ -carotene is a pigment that has a significant position in clearing free radicals, protecting the cell against destructive rays such as UV, regulating immunity, and preventing cancer as a potential antioxidant. In the food industry,  $\beta$ -carotene can be utilized to color foods and preserve the color of fruit juices. It can also be mixed with feeds to color salmon, trout, shellfish, and poultry meat (Ben-Amotz, 1999; Garcia-Gonzalez et al., 2000; Santin-Montanya, 2007; Takagi et al., 2005).

A green microalga, *Dunaliella* sp. (Chlorophyceae) has achieved a critical point in algal biotechnology with the  $\beta$ -carotene production. Under salt and/or light stress conditions, *Dunaliella* spp. can accumulate  $\beta$ -carotene between 2-5% of its dry weight, depending on the system utilized.

*Dunaliella* spp. naturally spread in saltwork fields such as in Ayvalık Tuzlası, Çamaltı Tuzlası, etc. in Türkiye. However,  $\beta$ -carotene production of natural species of *Dunaliella* in Türkiye is very limited. For this reason, this study was conducted to produce *Dunaliella viridis* biomass and  $\beta$ -carotene production and to explore inexpensive natural  $\beta$ -carotene sources assembled in our country that can be used in coloring fish, in cosmetic products such as blush, lipstick, and UV-protected sunscreens, and as vitamin A pills.

This study was carried out to determine vegetative growth yield and  $\beta$ -carotene production of the green algae *Dunaliella viridis* cultured under laboratory conditions. During the experiments, the vegetative growth of *D. viridis* was achieved at  $67 \mu\text{mol m}^{-2}\text{s}^{-1}$  light density, while at  $8000 \mu\text{mol m}^{-2}\text{s}^{-1}$  light intensity, Cystic *Dunaliella* cell formation started in the 5th week of the experiment followed by  $\beta$ -carotene production in the system and  $\beta$ -carotene amount accumulated in *D. viridis* was measured as  $2,542.12 \pm 781.35 \mu\text{g.g}^{-1}$  of dry weight (dw).

**Keywords:** *Dunaliella viridis*, Chlorophyceae, Natural and Functional Pigments, Chlorophyll,  $\beta$ -carotene

#### 1.Introduction

Algae (algae), one of the most significant aquatic organisms, are used by people as a food source, particularly in the Far East countries, due to the protein, carbohydrates, fatty acids, vitamins, mineral pigments, and many additional essential products they amass in the cell. In addition to their use as nutrients, they are the specialization of interest of many sectors due to the valuable bioactive products they include. Today, valuable products acquired from many algae species are cultivated and considered commercially. These natural products obtained from algae find markets in pharmaceutical and nutraceutical nutritional products and cosmetics (Mehar-MU et al., 2019).

Pigments acquired from algae are one of the most studied issues in recent years. Today, commercially cultivated microalgae and their most influential pigments; Beta-carotene ( $\beta$ -carotene) from *Dunaliella* sp, phycocyanin from *Spirulina platensis*, astaxanthin from *Haematococcus pluvialis*, and phycoerythrin from *Porphyridium cruentum*.

$\beta$ -carotene is a pigment that has a significant position in clearing free radicals, protecting the cell against destructive rays such as UV, regulating immunity, and preventing cancer as a potential

antioxidant. In the food industry,  $\beta$ -carotene can be utilized to color foods and preserve the color of fruit juices. It can also be mixed with feeds to color salmon, trout, shellfish, and poultry meat (Ben-Amotz, 1999; Garcia-Gonzalez et al., 2000; Santin-Montanya, 2007; Takagi et al., 2005).

Accelerating the studies on the production of  $\beta$ -carotene from *Dunaliella viridis* will be very advantageous for our country. Carotenoids are imported from abroad at high costs. Nevertheless in the waters of our country, our own *Dunaliella* naturally spreads in our salt fields (for example, Ayvalık, Çamaltı Tuzlası, etc.). It is of great significance to explore inexpensive natural  $\beta$ -carotene sources assembled in our country that can be used in coloring fish, in cosmetic products such as blush, lipstick, and UV-protected sunscreens and as vitamin A pills.

*Dunaliella sp.* (Chlorophyceae) has achieved a critical point in algal biotechnology with the  $\beta$ -carotene pigment that it accumulates in the cell under high light and salinity stress conditions. It accumulates  $\beta$ -carotene between 2-5% of its dry weight, depending on the system utilized, especially in the sun in 4-5 days.  $\beta$ -carotene is a carotenoid with an anti-oxidant impact not only because of the red color it includes but also because it is provitamin A (precursor vitamin A). While  $\beta$ -carotene can be synthesized by only a few living things in nature, most living things have to meet these needs with the nutrients they get from the outside. It is possible to meet this either by directly consuming the creatures including this pigment or by adding it from the outside to their feed. *Dunaliella viridis* has evolved an algae species that has attracted a lots of attention in recent years because it naturally synthesizes  $\beta$ -carotene at a high rate.

*Dunaliella viridis* is a unicellular green marine algae, a member of the order Volvales, belonging to the category Teodoresco Chlorophyceae (Ben-Amotz et al., 2009). The evolution step of *Dunaliella viridis* has both a motile and a stagnant form. It is oval, in shape 1– 10  $\mu\text{m}$  wide, 5 -20  $\mu\text{m}$  long. Cells have two long flagella of equal length and a cube-shaped chloroplast that occupies about half of the cell volume. *Dunaliella* species do not have dense cell walls (Gibbs and Duffus, 1976, Cirik, 1996; Santin-Montanya, 2007). Cells are surrounded by cellulosic glycoprotein configurations consisting of fibrils of 25-200  $\mu\text{m}$  in length (Gibbs and Duffus, 1976; Oliveira et al., 1980; Santin-Montanya, 2007). This supplies an advantage in changing the cell shape and adapting to osmotic changes. Therefore, osmoregulation is provided by increasing the glycerol concentration in the cell against extracellular osmotic pressure in the salt pans where this species commonly survives. This present work aimed to determine the intense production of *Dunaliella viridis* in vegetative cultures and its quantification by improving the accumulation of  $\beta$ -carotene in algae under high light conditions.

## 2. MATERIALS AND METHOD

### 2.1. Materials

#### 2.1.1. *Dunaliella viridis*

The pure culture of the green microalgae *Dunaliella viridis* supplied from the Algae Culture Collection of Ege University Fisheries Faculty, Department of Aquaculture. The adaptation of the species was supplied in Ege University Aquaculture Algae Laboratory, and it was reproduced from small magnitudes to larger magnitudes.

The taxonomy of *Dunaliella viridis* as follows:

- Division: Chlorophyta
- Classis: Chlorophyceae
- Ordo: Volvales
- Family: Dunaliellaceae
- Genus: *Dunaliella*
- Species: *Dunaliella viridis* Teodoresco 1906

*Dunaliella viridis* is oval in shape, 1–10 µm wide, 5–20 µm long. Cells have two long flagella of equal length and a cube-shaped chloroplast that occupies about half of the cell volume. *Dunaliella* species do not have thick cell walls (Gibbs and Duffus, 1976, Cirik, 1996; Santin-Montanya, 2007). Cells are surrounded by cellulosic glycoprotein structures consisting of fibrils of 25–200 µm in length (Gibbs and Duffus, 1976; Oliveira et al., 1980; Santin-Montanya, 2007). This provides an advantage in changing the cell shape and adapting to osmotic changes. Thus, osmoregulation is provided by increasing the glycerol concentration in the cell against the extracellular osmotic pressure in the salt pans where this species generally survives.

*Dunaliella viridis* vegetative cells grow at an optimum temperature of 25–28 °C, in the pH range of 6–8, at an illumination intensity of 25–100 µmol m<sup>-2</sup>s<sup>-1</sup> (Han, Sun et al., 2023).

### 2.1.2. Culture Medium

In the culture of *Dunaliella viridis*, Erdschreiber medium was used (Table 2.1). Firstly, for the Erdschreiber medium; NaNO<sub>3</sub> and Na<sub>2</sub>HPO<sub>4</sub>·7H<sub>2</sub>O solutions were prepared by dissolving 59.5 g NaNO<sub>3</sub> and 0.83 g Na<sub>2</sub>HPO<sub>4</sub>·7H<sub>2</sub>O each in 1000 ml distilled water. The Erdschreiber environment is shown in Table 2.1.

**Table 2.1** Erdschreiber medium

Composites	Amount Used in 3 L of Culture Media	Stock Solution Concentration	Final Concentration
NaNO <sub>3</sub> solution	10 ml	0.7 M	2.3 mM
Na <sub>2</sub> HPO <sub>4</sub> ·7H <sub>2</sub> O solution	10 ml	0.02 M	0.067 mM
Soil Extract	150 ml		
Vitamin B <sub>12</sub>	3 ml		
P-IV metal solution	36 ml		

#### 2.1.2.1. Preparation of Soil Extract

One kg of finely sieved non-fertilized garden soil was boiled with 2 L of tap water for one hour and the boiled mixture was kept in an autoclave for 60 minutes at 121 °C, 1 atmosphere vapor pressure to dissolve the minerals in the soil and release them into the water. The suspension, which was enabled to cool, was filtered through filter paper. After filtration, the remaining very fine sludge was settled by centrifugation and cleaned (Cirik and Gökpınar, 1999). 150 ml of the obtained mineral-rich golden yellow liquid was added to the Erdschreiber medium belonging to the control nitrogen group.

#### 2.1.2.3. Preparation of the vitamin solution

0.027 g of vitamin B<sub>12</sub> was mixed until dissolved in 200 ml of distilled water and added to 3 ml of Erdschreiber medium.

#### 2.1.2.4. Preparation of P-IV Metal Solution

The compounds in Table 2.2 were dissolved in 950 ml of distilled water and 36 ml of the prepared solution was added to the Erdschreiber medium.

**Table 2.2.P-IV** metal solution

Composites	Amount	Final Concentration
Na <sub>2</sub> EDTA.2H <sub>2</sub> O	0.75 g.L <sup>-1</sup>	2 mM
FeCl <sub>3</sub> .6H <sub>2</sub> O	0.097 g.L <sup>-1</sup>	0.36 mM
MnCl <sub>2</sub> .4H <sub>2</sub> O	0.041 g.L <sup>-1</sup>	0.21 mM
ZnCl <sub>2</sub>	0.005 g.L <sup>-1</sup>	0.037 mM
CoCl <sub>2</sub> .6H <sub>2</sub> O	0.002 g.L <sup>-1</sup>	0.0084 mM
Na <sub>2</sub> MoO <sub>4</sub> .2H <sub>2</sub> O	0.004 g.L <sup>-1</sup>	0.017 mM

### 2.1.3. *Dunaliella viridis* Stock Cultivations

To be utilized in the experimentation, vegetative *Dunaliella viridis* cultivation was reproduced in the Algal Technology laboratory of Ege University Fisheries Faculty. For this objective, stock cultivation were cultivated in 250 ml flasks and used for inoculation of 1 liter flasks to increase the culture volumes. In order to create the optimum conditions, the room temperature was adjusted to 20±2 °C with an air conditioner and the cultures were kept in laboratory conditions with continuous illumination at a light intensity of 67 μmol m<sup>-2</sup>s<sup>-1</sup>.

### 2.1.4. Harvest

*Dunaliella viridis* cells were harvested with a centrifuge at 3500 rpm for 5 minutes until cells were assembled at the bottom of the tubes.

## 2.2. Method

### 2.2.1. Trial Plan

Experiments with *Dunaliella viridis*, in which vegetative growth and β-carotene accumulation were performed, were carried out in 2 trials. During the study, cell count and optical density (OD) measurements were taken.

#### 2.2.1.1. Trial (1) (Vegetative Cell Growth)

In this experiment, which was planned as three repetitions, 1 L glass flasks were used with 950 ml of Erdschreiber culture medium after sterilized in an autoclave at 121 °C for 30 minutes, and after cooling, 50 ml of inoculum (*Dunaliella viridis* cells from stock cultures) was added into the flasks. Cultures were kept at a light intensity of 67 μmol m<sup>-2</sup>s<sup>-1</sup> during the vegetative cell growth phase. Cell counts with 3 replicates were taken daily with the aid of a Thoma-type Hemacytometer and 3 ml of sample for OD (optical density) measurements were taken at 680 nm with the aid of spectrophotometer (Model: Boeco S-20).

#### 2.2.1.2. Trial (2) (β-carotene Production)

β-carotene production, which is one of the targets of our study. In this part of the experiment, high light intensity of 8000 μmol m<sup>-2</sup>s<sup>-1</sup> was applied to generate cyst formation(β-carotene) after the completion of vegetative growth of *Dunaliella viridis*. The ambient temperature in the laboratory was set to 20 °C and 3 ml of sample was taken daily for cell counts and OD measurements with 3 replicates. The experiment was terminated at the point where the daily cell number and OD values started to stay constant or started to decrease and cells were harvested by centrifuge at 3500 rpm in 15 ml glass tubes (Model: Electro Mog M615 P).

### 2.2.2. Analysis During the Trial Period

#### 2.2.2.1. Total Chlorophyll (a and b) and β-carotene Analysis Method and Determination of Amounts

Acetone (99 % purity) was utilized for the isolation of pigments and the extraction of the pigments as followed the procedure mentioned below:

- *Dunaliella viridis* cells are weighed on the balance (Model: Baster)
  - Acetone (99 % purity) is added, as 50 ml for each gram of *Dunaliella viridis* cells,
  - It is homogenized with a hand blender at 1000 rpm for 1 minute,
  - The bottom part, which is filtered through the filter, is centrifuged at 2500 rpm for 10 minutes,
  - Taking the upper part, it is read in the spectrophotometer at 662 nm for Chlorophyll-a, 646 nm for Chlorophyll-b and 470 nm for  $\beta$ -carotene,
  - The readings are calculated using the following formulas:
  - Chlorophyll-a, Chlorophyll-b, and  $\beta$ -carotene amounts are calculated by using the formulas written below:
- 
- $\text{Chla} = \text{Chlorophyll-a } (\mu\text{g.g}^{-1}) = 11.75 * A_{662} - 2.35 * A_{646}$
  - $\text{Chlb} = \text{Chlorophyll-b } (\mu\text{g.g}^{-1}) = 18.61 * A_{646} - 3.96 * A_{662}$
  - $\beta\text{-carotene } (\mu\text{g.g}^{-1}) = (1000 * A_{470} - 2.27 * \text{Chla} - 81.4 * \text{Chlb}) \div 227$  (Lichtenthaler and Wellburn, 1985)

### 2.2.3. Statistical Analysis

All data belonging to the analysis were specified using the T-Test in the SPSS statistical program to determine whether there was a statistical dissimilarity between the amounts of Total Chlorophyll (a and b) and  $\beta$ -carotene at the commencement and end of the trial ( $P \leq 0.05$ ). The data of the cell number, optical density, temperature, salinity, pH, and oxygen values obtained during the study were analyzed with MEANS in the SPSS statistical program. All consequences are defined as mean  $\pm$  standard deviation.

## 3. RESULTS

Temperature ( $^{\circ}\text{C}$ ), PH,  $\text{O}_2$  ( $\text{mg. L}^{-1}$ ), light intensity ( $\mu\text{mol m}^{-2}\text{s}^{-1}$ ) measurements were taken, cell counts, optical density, chlorophyll-a+b ( $\mu\text{g.g}^{-1}$ ) and  $\beta$ -carotene ( $\mu\text{g.g}^{-1}$ ) amounts were determined. The mentioned stress factor (light intensity) was applied in the second trial after the first trial.

### 3.1. Trial (1)

#### Optic densitiy

In this experiment, light intensity of  $67 \mu\text{mol m}^{-2}\text{s}^{-1}$  was provided for vegetative growth study. The initial optical density values were found to be  $0.039 \pm 0.07$  at the beginning and  $0.77 \pm 0.03$  at the end of the experiment. (Figure 3.1.)

The temperature varied between  $22 \pm 2.44$   $^{\circ}\text{C}$ , PH  $7.5 \pm 1.52$ ,  $\text{O}_2$   $8 \pm 2.54$   $\text{mg.L}^{-1}$  and salinity  $\%70 \pm 0.0$  throughout the experiment.

**Figure 3.1.** Vegetatif growth (OD values at Abs 680 ) of *D. viridis* at  $67 \mu\text{mol m}^{-2}\text{s}^{-1}$  light intensity at Lab conditions.

#### Number of the cells

While the initial cell count value was found to be  $100,000 \pm 0.00$  at the beginning and  $185,000 \pm 13.29$  at the end of the experiment (Figure 3.2.).

During the Trial 1 experiment, the temperature was  $22 \pm 2.44$  °C, PH was  $7.5 \pm 1.52$ ,  $\text{O}_2$  was  $8 \pm 2.54$   $\text{mg.L}^{-1}$  and the salinity was  $70 \pm 0.0$  ppt throughout the experiment conducted under  $67 \mu\text{mol m}^{-2}\text{s}^{-1}$  light intensity.

**Figure 3.2** Vegetatif growth (number of the cells per ml) of *D. viridis* at  $67 \mu\text{mol m}^{-2}\text{s}^{-1}$  light intensity at Lab conditions.

#### Total Chlorophyll

In the 5th week of the experiment, it was found that that the cell number and optical density values remained at constant levels and at this point the cultivation experiment was terminated. It was determined that cyst formation or  $\beta$ -carotene production would be achieved under  $67 \mu\text{mol m}^{-2}\text{s}^{-1}$  illumination conditions after 5 weeks of vegetative growth.

While some of the harvested cells at the end of the experiment were separated for pigment (Total Chlorophyll (Chlorophyll-a + Chlorophyll-b) and  $\beta$ -carotene) analyzes (Figure 3. and Figure 4.), the rest were used for following experiment called Trial 2.

At the beginning of the trials, the amount of Total Chlorophyll (Chlorophyll a+ Chlorophyll b) was  $521.33 \pm 125.32$  ( $\mu\text{g}\cdot\text{g}^{-1}$ ) and reached to  $2,320.32 \pm 377.21$  ( $\mu\text{g}\cdot\text{g}^{-1}$ ) at the end of the trial (Figure 3.3).

**Figure 3.3** Total Chlorophyll (Chlorophyll a+ Chlorophyll b) amounts ( $\mu\text{g}\cdot\text{g}^{-1}$ ) at the beginning and end of the experiments at  $67 \mu\text{mol m}^{-2}\text{s}^{-1}$  light intensity Lab condition.

### 3.2. Trial (2) $\beta$ -carotene production

At this experiment, the algae cells whose vegetative growth was achieved in Trial 1 were harvested and transferred to fresh Erdschreiber medium and exposed to  $8000 \mu\text{mol m}^{-2}\text{s}^{-1}$  light intensity (light stress).

While the initial optical density values were found to be  $0.022 \pm 0.03$  at the beginning of the experiment, when found as  $0.25 \pm 0.03$  at the end of the experiment (Figure 3.4.). Temperature varied between  $27 \pm 2.30$  °C, PH  $8.5 \pm 1.52$ ,  $\text{O}_2$   $9 \pm 2.54$   $\text{mg}\cdot\text{L}^{-1}$  and salinity  $190 \pm 78.63\%$  throughout the experiment.

**Figure 3.4.** Optical density (OD values at Abs 680 ) of *D.viridis* at  $8000 \mu\text{mol m}^{-2}\text{s}^{-1}$ .

### Cell number

While the initial cell count was  $50,000 \pm 0.00$  at the beginning of the experiment, 5 week later it reached to  $65,000 \pm 3.29$  at the end of the experiment.

Temperature was  $27 \pm 2.30$  °C, PH was  $8.5 \pm 1.52$ , O<sub>2</sub> was  $9 \pm 2.54$  mg.L<sup>-1</sup> and salinity was  $190 \pm 78.63$  ppt throughout the experiment conducted under  $8000 \mu\text{mol m}^{-2}\text{s}^{-1}$  light intensity was applied during the experiment is given in Figure 3.5.

Figure 3.5. Cell number (number per ml) of *D. viridis* at  $8000 \mu\text{mol m}^{-2}\text{s}^{-1}$ .

### Total Chlorophyll

At the beginning of the trials, Total Chlorophyll (Chlorophyll a+ Chlorophyll b) amount was  $1.649.28 \pm 319.55$  ( $\mu\text{g.g}^{-1}$ ), while it decreased to  $30.52 \pm 3.21$  ( $\mu\text{g.g}^{-1}$ ) at the 5th week of the experiment (Figure 3.6).

Figure 3.6. Total Chlorophyll (Chlorophyll a+ Chlorophyll b) amounts ( $\mu\text{g.g}^{-1}$ ) at the beginning and end of the experiments at  $8000 \mu\text{mol m}^{-2}\text{s}^{-1}$ .

### $\beta$ -carotene amounts

$\beta$ -carotene amount was  $40.23 \pm 5.52$  ( $\mu\text{g.g}^{-1}$ ) at the beginning, when it increased to  $2,542.12 \pm 781.35$  ( $\mu\text{g.g}^{-1}$ ) at the end of the 5th week of the experiment (Figure 3.7).

**Figure 3.7.** .  $\beta$ -carotene amounts ( $\mu\text{g}\cdot\text{g}^{-1}$ ) at the beginning and end of the experiments at  $8000 \mu\text{mol m}^{-2}\text{s}^{-1}$ .

#### 4. Discussion

*Dunaliella viridis* (Chlorophyceae) has achieved a critical point in algal biotechnology with the  $\beta$ -carotene pigment that it accumulates in the cell under high light and salinity stress circumstances. It accumulates  $\beta$ -carotene between 2-5% of its dry weight, depending on the system utilized, especially in the sun in 4-5 days (Lai Et al., 2022).  $\beta$ -carotene is a carotenoid with an anti-oxidant impact not only because of the red color it includes but also because it is provitamin A (precursor vitamin A). While  $\beta$ -carotene can be synthesized by only a few living things in nature, most living things have to meet these needs with the nutrients they get from the outside. It is possible to meet this either by directly consuming the creatures including this pigment or by adding it from the outside to their feed. *Dunaliella viridis* has evolved an algae species that has attracted a lots of attention in recent years because it naturally synthesizes  $\beta$ -carotene at a high rate.

Carotenes are of vital importance for human health because they protect cell roots and tissues from harmful factors as biological antioxidants. Moreover, many researchers have suggested carotenoids as protective against human diseases, and also carotenes such as  $\beta$ -carotene and lutein have been still used in cancer treatment (Richmond 2000; Ziegler et al. 1996). The main pigments in *Dunaliella viridis* are Chlorophyll-a, Chlorophyll-b, and betacarotene. In addition, this microalg contain secondary carotene groups such as canthaxanthin and astaxanthin. Secondary carotenoids are produced under extreme conditions such as high light intensity. Particularly, the change of color from green to red-orange as a result of nutrient restriction has been associated with an increase in secondary carotenes (Lubian et al., 2000). They also reported a decrease in chlorophyll-a and total carotene values due to the increase in light intensity in algae. Algal pigments are products presented in the beauty and health products market as various creams, milk, lotions, mud, face, and body masks. Chlorophyll is a green pigment substance that absorbs light of various wavelengths and provides photosynthesis (assimilation) to occur in the plant. Chlorophyll is responsible for absorbing the light energy used in photosynthesis, the reduction of carbon dioxide to other plant substances and sugars. Carotene has a significant role in photosynthesis as a photosynthetic pigment. Carotene can be stored in the liver and converted to vitamin A when needed, consequently, it's considered a provitamin. It is to photosynthesis by transferring the absorbed light to chlorophyll. It is responsible for providing the orange color of carrots and most other vegetables and fruits.  $\beta$ -Carotene is the widespread form. Leafy fruits and vegetables such as colors green, orange or yellow are contained a high level of  $\beta$ - carotene. In addition, brown algae contain carotene. Carotene is also effective against skin aging besides protecting the skin from the harmful rays of the sun (Cirik 1989, Cirik and Cirik 1999, Cirik and Gökpinar 1999; Cirik).

$\beta$ -carotene is a pigment that has a significant position in clearing free radicals, protecting the cell against destructive rays such as UV, regulating immunity, and preventing cancer as a potential

antioxidant. In the food industry,  $\beta$ -carotene can be utilized to color foods and preserve the color of fruit juices. It can also be mixed with feeds to color salmon, trout, shellfish, and poultry meat (Ben-Amotz, 1999; Garcia-Gonzalez et al., 2000; Santin-Montanya, 2007; Takagi et al., 2005).

Cultivation,  $\beta$ -carotene production, and quantification of *Dunaliella viridis* under laboratory conditions were defined in this study. Some major conditional processes and steps can be ordered on growth algae. environmental conditions can cause changes in algal growth and algal biochemical structure. It affects growth, nutrient concentrations as well as the type of nutrients used in the nutrient medium (Brown et al. 1989). In the culture of *Dunaliella viridis*, Erdschreiber medium was used. Moreover, it is clearly observed that changes in temperature, light and salinity affect the growth and biochemical structures of algae (Mesude İsar et al., 2022). In order to create the optimum conditions, the room temperature was adjusted to  $20 \pm 2$  °C with an air conditioner and the cultures were kept in laboratory conditions with continuous illumination at a light intensity of  $67 \mu\text{mol m}^{-2}\text{s}^{-1}$ .

Cystic stage trials with *Dunaliella viridis*, in which vegetative expansion and  $\beta$ -carotene accumulation were performed, were carried out in 2 stages. Metamorphosis in cultivations was determined by cell count and optical density (OD) measurements.

## 5. Conclusion

In the scope of this research, aquaculture protocols and pigment compositions of *Dunaliella viridis*, which are naturally distributed in our waters, were examined and found that  $\beta$ -carotene was  $40.23 \pm 5.52 (\mu\text{g.g}^{-1})$  at the beginning, it increased to  $2,542.12 \pm 781.35 (\mu\text{g.g}^{-1})$  at the end of the experiment 5th week. This result is similar to the previous studies. Potential usage of  $\beta$ -carotene particularly in the field of cosmetics, neuroceuticals, and food should be studied in future research activities.

#### Özet

Poliüretanlar sağlıktan inşaat sektörüne kadar oldukça farklı alanlarda yaygın kullanım alanına sahip polimerik malzemelerdir. Poliüretanlar diizosiyanatların ve diollerin reaksiyonuyla elde edilmektedirler. Bu reaksiyon sonunda elde edilen polimerler lineer olup çözünürdürler. Ancak ikiden fazla izosiyanat ve hidroksil grubuna sahip reaktiflerle sentezlendiğinde termoset malzemeler elde edilmektedir. Günümüzdeki en büyük problemlerden bir tanesi polimerlerin çevre ile olan etkileşimidir. Biyo esaslı poliüretanların yapısına bakıldığında genellikle diol (poliol) komponentinin biyo esaslı olduğu görülmektedir. Bu çalışmamızda biyo esaslı bir diol olan mono olein daha çevreci bir metot olan borik asit esteri asidolizi reaksiyonu ve atık zeytinyağından elde edilen oleik asit ile sentezlenmiştir. Daha sonra elde edilen mono olein MDI ve H-MDI ile polimerize edilerek lineer doymamış poliüretanlar sentezlenmiştir. Bu doymamış poliüretanlar sahip olduğu çift bağ sebebiyle vulkanizasyondan halojenlendirme reaksiyonuna kadar birçok reaksiyonu verebilmektedir. Bu polimerlerin daha sonradan modifikasyonunu yapmak mümkündür. Elde edilen tüm ara maddelerin ve polimerlerin spektral karakterizasyonları bu çalışmada yapılmıştır.

**Anahtar Kelimeler:** Yenilenebilir kaynaklar, Bitkisel trigliseritler, monoolein, doymamış poliüretanlar, borik asit esteri

#### Synthesis and characterization of unsaturated polyurethanes from renewable resources

#### Abstract

Polyurethanes are polymeric materials that have widespread applications in many areas such as, healthcare and construction industries. Polyurethanes are obtained by the reaction of diisocyanates and diols. The polymers obtained at the end of this reaction are linear and soluble. However, thermoset materials are obtained when synthesized with reagents having more than two isocyanate and hydroxyl groups. One of the biggest problems today is the interaction of polymers with the environment. When the structure of bio-based polyurethanes is examined, it is generally seen that the diol (polyol) component is bio-based. In this study, mono olein, a bio-based diol, was synthesized by boric acid ester acidolysis reaction, which is a more environmentally friendly method, and oleic acid obtained from waste olive oil. Then, the obtained mono olein was polymerized with MDI and H-MDI to synthesize linear unsaturated polyurethanes. These unsaturated polyurethanes can undergo many reactions, from vulcanization to halogenation reaction, due to the double bond they have. It is possible to modify these polymers later. Spectral characterizations of all obtained intermediates and polymers were performed in this study.

**Keywords:** Renewable resources, Vegetable triglycerides, monoolein, unsaturated polyurethanes, boric acid ester.

#### GİRİŞ

Fosil kökenli kaynakların giderek azalması ve bunların gerek üretimleri sonucu gerekse bu kaynaklardan elde edilen malzemelerin sentezinde uygulanan yöntemler sebebiyle çevreye de çok olumsuz etkileri olmaktadır. Bu sebeplerle yenilenebilir kaynaklardan elde edilen malzemeler konusunda yoğun çalışmalar sürdürülmektedir. Yenilenebilir kaynaklar bitkisel, hayvansal veya mikroorganizma kökenli olabilir. Bu kaynaklardan çok çeşitli monomer ve polimerler elde edilebilir (Kapluhan 2014, Özdemir 2013).

Polimerler içerisinde poliüretanlar, uygulama kolaylıkları, reaktiviteleri, termal ve mekanik özelliklerinin üstünlüğü sebebiyle inşaat sektöründen, medikal sektörüne kadar oldukça fazla alanda uygulanma imkânına sahip malzemelerdir. Poliüretanlar diizosiyanat ve diollerin reaksiyonları ile elde edilirler. Diollerin yapısı kolay bir şekilde değiştirilebilmektedir. Diol bileşeni olarak polyester, polieter veya poliamid esaslı dioller kullanılabilir gibi etilen glikol, propilen glikol, tetrametilen glikol gibi basit yapıya sahip maddelerde olabilir (Petrovic 2007).

Yine bir kısım poliüretan tıpkı kauçuklar gibi yüksek gerilmeye sahip polimerlerdir, tıpkı kauçuk malzemeler gibi orijinal boylarının %300 veya 400 ü gibi yüksek gerilme gösterirler. Kauçuktan farklı olarak poliüretanlar uygun koşullar altında başlangıç maddelerine kadar parçalanabilirler. Başlangıç maddelerinden olan izosiyanatlar elde edilemeyeceği için bunların yerine aminleri işlem sonunda elde edilir (Bhavsar 2023, Kaur 2022).

Bu çalışmada yenilenebilir bir kaynak olan bitkisel trigliseritlerden yola çıkarak doymamış poliüretanların sentezi ve karakterizasyonu anlatılmıştır. Çalışmanın ilk aşamasında borik asit asidolizi ile monoolein sentezlenmiştir. Daha sonraki basamakta ise elde edilen bu monoolein MDI (metilen difenildiizosiyanat) ve HMDI (hidrojene metilendifenil diizosiyanat) kullanılarak polimerize edilmiş ve FTIR yöntemi ile karakterize edilmiştir.

## MATERYAL VE METOT

Bu çalışmada borik asit esteri sentezlerken kullanılan borik asit ve gliserin Merck® firmasından toluen ise Sigma Aldrich® firmasından satın alınmıştır. Oleik asit ise Kırlangıç® zeytinyağının saponifikasyonu ve daha sonra asitlendirilmesiyle elde edilmiş ve burada kullanılan sodyum hidroksit ve klorik asit Merck® firmasından satın alınmıştır. Mono olein sentezlenirken de başlangıç maddeleri dışında kullanılan p-toluen sülfonik asit, klorik asit, diklorometan ve sodyum sülfat da Merck® firmasından satın alınmıştır. Elde edilen son ürün olan mono olein; %75 oleik asit, %5 stearik asit ve %5 çoklu doymamış yağ asidi içermektedir. Başlangıç maddeleri ve son ürünün infrared (FTIR) spektrumları için Vertex® V70 model spektrofotometre kullanılmıştır.

### Oleik Asit Eldesi:

500 mililitrelik bir behere 100 gram zeytinyağı konur. Üzerine 24 gram %50'lik sodyum hidroksit çözeltisi konur. 80 °C'de 2 saat karıştırılır ve süre sonunda tamamen sabunlaşmış kütle üzerine 200 mililitre distile su ilave edilir. Sabun kütlelerinin tamamının çözünmesi sağlanır. Daha sonra bu karışım üzerine azar azar 35 mililitre konsantre klorik asit çözeltisi ilave edilir. Karışım bu şekilde 2 saat kadar daha karıştırılır. Daha sonra ayırma hunisinde üst faz olan oleik asit kısmı alınır. Vakum fırınında 50 °C'de bir gece bekletilerek içinde suyun uçurulması sağlanır. Elde edilen bu oleik asit herhangi bir saflaştırma işlemine tabii tutulmadan daha sonraki işlemlerde kullanılmıştır.

### Monoolein Sentezi:

250 mililitrelik bir dibi düz balona elde edilen 21.02 gram trigliseril borat konur. Üzerine 26,58 g oleik asit ve katalist olarak 0.41 g para toluen sülfonik asit (PTSA) eklenir. 2 saat boyunca 170 °C'de yağ banyosunda reflüks edilir. Mono olein oluştuktan sonra üzerine 100 mililitre %5'lik klorik asit eklenir ve kuvvetlice karıştırılır. Bu işlemten sonra karışım 50 mililitre diklorometan ile 3 kere yıkanır. Su çekmesi için içine sodyum sülfat katılır ve süzülüp kurutulur. Son olarak döner karıştırıcıda diklorometan uçurulur. Elde edilen monoolein başka bir saflaştırma işlemi yapılmadan kullanılır.

### Doymamış poliüretan sentezi:

50 ml lik bir behere 3,57 g monoolein ve 2,5 g MDI katılır. İyice karıştırılan örnek daha sonra bir kalıba dökülür. Örnek 24 saat oda sıcaklığında daha sonra ise 80 °C sıcaklıkta fırında bekletilir.

Hidrojenize MDI poliüretanları içinse yine 50 ml lik bir behere 3,57 g monoolein ve 2,6 g MDI katılır. İyice karıştırılan örnek daha sonra bir kalıba dökülür. Örnek 24 saat oda sıcaklığında daha sonra ise 80 °C sıcaklıkta fırında bekletilir.

## BULGULAR ve TARTIŞMA

### Monoolein Sentezi:

Monoolein sentezi yeni bir yöntem olan borik asit esteri asidolizi ile gerçekleştirilmiştir. Bu sentezin ilk aşamasında gliserin borik asit ile reaksiyon sokulmuş ve reaksiyon sonunda açığa çıkan su, su tuzağı ile tutulmuştur. Reaksiyonun bittiği su miktarı ile takip edilebilmiştir. Borik asit esteri yaklaşık 2 saatlik bir reaksiyon sonucu saf olarak elde edilmiştir.

Daha sonraki basamaklarda ise gliserin borik asit esteri (trigliseril borat) oleik asit ile 2 saatlik reaksiyon sonunda monooleine dönüştürülmüştür. Elde edilen monooleinin verimi %97 ve saflığı ise en az %75 olarak bulunmuştur. Oleik asit ve monooleinin FTIR leri şekil 1 de verilmektedir.

Şekil 1. Oleik asit (üst) ve Monoolein (alt) FTIR spektrumları.

### Doymamış Poliüretanların Sentezi ve FTIR Karakterizasyonu

Monooleinin MDI ve HMDI ile polimerizasyonu sonucu oluşan poliüretanlar lineer yapıda olup dietil eter, kloroform, tetrahidrofuran, toluen gibi solventlerde çözünmektedirler. Yekpare köpüksüz poliüretan eldesi için prosedürlerde tarif edilen miktar monoolein ve diizosiyanat oda sıcaklığında bir gün bekletilmeli daha sonra ise etüvde 80 °C ta yine 24 saat kürlendirilmelidir.

Elde edilen doymamış poliüretanların FTIR spektrumları şekil 2 ve 3 te gösterilmektedir. Her iki spektrumda oluşan poliüretan gruplarındaki azota bağlı hidrojen atomu 3300 cm<sup>-1</sup> de zayıf ve geniş bir amid A piki vermektedir. Monooleindeki ester grubu piki yine 1740 ta görülmektedir. Bu pikin yanında amid I bandından kaynaklanan 1710 cm<sup>-1</sup> de ve 1633 cm<sup>-1</sup> yeni pikler gelmiştir. Amit II bandından kaynaklanan 1470 ve 1570 cm<sup>-1</sup> arasında yeni pikler gözlenmiştir. İlave olarak 1250-1350 cm<sup>-1</sup> bölgesinde amid III bandı pikleri gözlenmiştir.

Şekil 2. Monoolein-HMDI poliüretanının FTIR spektrumu

Şekil 3. Monoolein-MDI poliüretanının FTIR spektrumu

## SONUÇ

Bu çalışma ile yenilenebilir kaynaklardan olan zeytinyağı veya fındık yağından yola çıkarak, monoolein sentezi anlatılmıştır. Elde edilen monoolein MDI ve HMDI ile reaksiyona sokulduğunda lineer doymamış poliüretanlar elde edilmiştir. Doymamışlık poliüretan zincirlerinde bulunan oleik asidin çift bağından ötürü ortaya çıkmaktadır.

#### Abstract

In this work, an efficient synthesis of antibacterial triglycerides from waste cooking oil was demonstrated. Epoxidized used cooking oil (EWO) and monochloroacetic acid (MCA) are combined in the synthesis. The next reaction is a quaternarization reaction involving tertiary amines. Quaternarization is carried out using pyridine and triethylamine. FTIR technique is used to characterize all materials synthesized. The resultant materials are cationic compounds and inherently antibacterial. Antibacterial activities were evaluated with *Escherichia coli* and *Staphylococcus aureus*. It was found that when compared to the Ciprofloxacin standard after 24 hours, the triethylammonium (QT-EWO-MCA) and pyridinium (QP-EWO-MCA) derivatives of used cooking oil demonstrated 87% and 92% inhibitory action for *Staphylococcus aureus*, respectively

**Keywords:** waste cooking oil, triglycerides, epoxidized plant oils, monochloroacetic acid, cationic oils, antibacterial activity

#### INTRODUCTION

The fatty acid three ester of glycerol is known as triglycerides. The majority of their uses are food-related. Cooking oil waste (WCO) is produced after the cooking process. WCOs have a detrimental effect on the environment, which affects human health. The amount of WCO increases linearly with global population. It is apparent that as the population grows, the amount of used cooking oil would as well. A crucial concern would be recycling those materials. It is not safe to use waste cooking oil for food purposes. Thus, it is necessary to find WCO's alternative application areas. For that purpose, the structure of WCO's should be modified (Joshi 2023, Kahraman 2021).

Due to the complex structure of the triglycerides, one can easily modify and obtain pure compounds and polymers. Ester functionalities, double bonds, allylic positions and  $\alpha$ -carbons to ester carbonyls are main reactive sites of a typical triglycerides (Cayli 2010).

In this study, epoxy derivative of waste cooking oil synthesized in the first step. Then EWO was reacted with monochloroacetic acid. When this chlorinated derivative is reacted with tertiary amines, quaternarization take place. Triethylamine and pyridine were used for modification. Those quaternary ammonium salts are water soluble and have anti-bacterial potential.

Figure 1. Structures of a-QT-EWO-MCA and b- QP-EWO-MCA

## MATERIALS AND METHODS

Chloroform, dichloromethane, Formic acid, 50% hydrogen peroxide, iodine monobromide, methylene blue indicator, monochloroacetic acid, potassium iodide, sodium dodecylbenzenesulfonate, sodium hydroxide, sodium iodide, sodium sulfate, sodium thiosulfate, and tetrahydrofuran were purchased from Merck (Darmstadt, Germany) and were used as received. Waste cooking oil (WCO) was obtained from a local restaurant. WCO was filtered and dried before use. Ciprofloxacin was purchased from Alfa Aesar (Kandel, Germany). FTIR characterization of compounds was performed by Nicolet 380 series ATR spectrometer using diamond window.

### Synthesis of Epoxidized Waste Cooking Oil

In a 250 ml round bottom flask, 50 g of dried and filtered WCO 28 g of formic acid was mixed. This mixture then was cooled with an ice bath. Then, 8 g of 50 % hydrogen peroxide solution was added drop-wise in 30 minutes. After that, the mixture was stirred for 16 hours. When the reaction was completed, 100 ml dichloromethane was added. Then mixture was washed with 100 ml tap water 3 times. The crude product was dried over dry sodium sulphate. EWO was used without any further purification.

### Synthesis of EWO-monochloroacetic acid condensate (EWO-MCA)

In a 50 ml round bottom flask, 9,5 g of EWO was mixed with 2,8 g of monochloroacetic acid. This mixture was heated to 120 oC and stirred under nitrogen atmosphere for 8 hours. Reaction was followed by measuring of acid number. After 8 hours, acid number was 0. EWO-MCA condensate was used without any further purification.

### Quaternarization of EWO-MCA

In a 250 ml round bottom flask, 12, 4 g of EWO-MCA was dissolved in 50 ml tetrahydrofuran. Then 3,4 g of triethylamine and 0,1 g of sodium iodide were added to this mixture. This mixture was refluxed for 24 hours. After that, solvent and excess triethylamine was removed by rotary evaporator. Triethylamine derivative of EWO-MCA (QT-EWO-MCA) was used without any further purification. In the case of pyridine derivative, 2,4 g of pyridine and 0,1 g of sodium iodide were added to EWO-MCA solution. Pyridine derivative (QP-EWO-MCA) was also used without any further purification.

## RESULTS and DISCUSSION

Standardized waste cooking oil was reacted with monochloroacetic acid, conversion was followed by acid number titration. Reaction temperature was set to 120 °C. Lower temperatures required longer reaction time. At the beginning of the reaction, acid number was measure as 135. When the reaction proceeded, acid number values decreased and closed to 0 after 8 hours at 120 °C. The highest conversion was measured as 97 % for QT-EWO-MCA and 95% for QP-EWO-MCA after 24 hours.

FTIR of pyridine and triethylamine derivative of EWO-MCA is exhibited in figure 2. When triethylamine group introduced a strong peak at 755 cm<sup>-1</sup> was determined. The peak at 785 cm<sup>-1</sup> shifted to 791 cm<sup>-1</sup> that showed all -CH<sub>2</sub>-Cl group reacted with triethylamine and they were converted to quaternary ammonium salts. In the case of pyridine, if EWO-MCA was reacted with pyridine, the peak at 785 cm<sup>-1</sup> shifted to 781 cm<sup>-1</sup> probably due to formation of pyridinium group. Another evidence of quaternarization the new peaks that were observed at 3061 and 1636 cm<sup>-1</sup>. Those peaks indicate the presence of vinylic hydrogens and carbon-carbon double bonds. Pyridine is an aromatic group and when is introduced EWO-MCA condensate, the peak appeared at 3062 and 1638 cm<sup>-1</sup>. Additionally, the peak at 1491 cm<sup>-1</sup> showed the presence of -HC=N- group.

Figure 3. FTIR spectrum of a-QT-EWO-MCA and b-QP-EWO-MCA

After 12 hours, inhibition percentage of QT-EWO-MCA was found 70 for *Staphylococcus aureus* and 63 for *Escherichia coli* respectively. The results for QP-EWO-MCA were 75% for *Staphylococcus aureus* and 70 % for *Escherichia coli*. The sensitivities of the QP-EWO-MCA and QT-EWO-MCA compounds were greater in *Staphylococcus aureus* than in *Escherichia coli*. After 24 hours, inhibition percentage of QT-EWO-MCA was determined as 87% for *Staphylococcus aureus* and 83% for *Escherichia coli* respectively. QP-EWO-MCA exhibited 92% inhibition for *Staphylococcus aureus* and 87% inhibition for *Escherichia coli*. These findings were quite meaningful when considering the cell wall structure of *Escherichia coli* and *Staphylococcus aureus*.

## CONCLUSION

This work describes an efficient synthesis of antibacterial triglycerides from waste cooking oil. The synthesis involves multiple steps, including epoxidation of the waste cooking oil, condensation reaction of epoxidized waste cooking oil with monochloro acetic acid, and quaternarization reaction with tertiary amines such as triethylamine and pyridine.

The results showed that the pyridine derivative had a better antibacterial activity than the triethylamine derivative. This work presents a promising approach for converting waste cooking oil into useful products with antibacterial properties

#### Abstract

The aim of this study is to investigate the biological activities of *Arenaria kotschyana* samples grown in middle Anatolia using different solvents. For this purpose, plant samples were extracted using ethanol, methanol and water. DPPH and CUPRAC methods were used to determine their antioxidant properties. Total phenolic content was also measured. According to the results obtained, the best antioxidant property was observed in the methanol extract with 69.54±0.14% for DPPH method. For CUPRAC method, 154.98±2.34 mg TE/g was observed in water extract. Furthermore, antioxidant properties were determined for each solvent. The highest total phenolic content was observed in methanol extract with 84±1.79 mg GAE/g. Our results suggested that the tested *A. kotschyana* could be valuable as source of natural agents in the development of health-promoting applications.

**Keywords:** Antioxidant, biological activity, total phenol, *Arenaria kotschyana*

#### INTRODUCTION

Plants remain significant sources of bioactive ingredients. Many secondary metabolites require extensive research to determine their potential as therapeutic agents. Recently, drug repositioning has emerged as an avenue for developing new therapeutic agents, and natural products have great potential in this field as they have been used for medical purposes for millennia (Huang and Zhang, 2022). Additionally, several natural compounds have been studied with restricted bioactivities, yet they possess the ability to evaluate new potential effects. Empirically, medicinal herbs have been used by humans with no rational knowledge of their pharmacological effects or active elements, learning by experience alone. In the early 19th century, plant-based rational drug discovery emerged, with an effort to combine the chemical composition with bioactivity (Atanasov et al., 2015). Although biotechnological drugs and monoclonal antibodies carry a significant value, medicinal plants present a distinct chance to explore new drugs through their extraordinary chemical diversity (Atanasov et al., 2021).

Plants are a plentiful source of phytochemicals such as flavonoids, anthocyanins, carotenoids, catechins, cinnamic acid derivatives, chalcones, stilbenes, and tocopherols, which have potential health benefits through their antioxidant properties (Rammohan et al., 2020). These phytochemicals have the ability to target multiple molecules and may serve as valuable agents for promoting health, especially considering that the pathophysiology of many illnesses involves multiple factors rather than a single cause (Efferth and Koch, 2011). Product safety necessitates careful consideration of pharmaceutical formulation, extraction, and manufacture, as well as the mode of action (Sut et al., 2016). To this end, medicinal plants should be scrutinised to discover potential antioxidants or enzyme inhibitors that could be employed as nutraceuticals, functional foods, or medications.

*Arenaria* genus belongs to the Caryophyllaceae family. The genus has 272 species that are distributed worldwide (Anonymous, 2023). *Arenaria* taxa are annual or perennial herbs, rarely spiny subshrubs, and often caespitose or mat-forming plants found in Eurasia, America, and North Africa. Their leaves lack stipules. The flower clusters, which can have as few as one or as many as fifty blooms, are found at the top or sometimes also on the sides of the stem. The shape of the leaves can range from round to slender and pointed. The flower

clusters, which can have as few as one or as many as fifty blooms, are found at the top or sometimes also on the sides of the stem. The clusters can be arranged in a branching panicle or a group of clusters. The flowers have five sepals. The petals are white and can be any of the following: free, herbaceous, scarious, or coriaceous. They may have a single midrib or one that is more prominent than the lateral veins, although sometimes they have an equally three-veined midrib. They may have a single midrib or one that is more prominent than the lateral veins, although sometimes they have an equally three-veined midrib. Entire or rarely subemarginate. They possess ten stamens, of which the outer five possess obsolete, single, or bipartite basal glands along with three styles. The capsule opening displays six teeth or occasionally six valves. The seeds are present inside. *Arenaria* can be either black or reddish, but the external morphological characteristics make distinguishing between the species a challenging task (Doğan and Çakır, 2019).

Hence, this study attempted to explore the phytochemical composition activity and investigate the antioxidant capabilities of *A. kotschyana*. Additionally, it also aimed to study the pharmacological potential of *A. kotschyana* against oxidative stres. It is also one of the aims of the study to determine the total phenolic content.

## MATERIALS AND METHODS

The aerial parts of the *A. kotschyana* species were collected during Summer 2020 from Central Anatolia Region of Turkey. The plant specimens were dried under shaded conditions at room temperature for approximately one week. Subsequently, the pulverisation process was carried out employing a mill, and the specimens were stored out of the light.

Extracts were prepared using ethanol, methanol, and water. The plant material (10 g) with 100 mL of solvents (ethanol, methanol, and water) was extracted with the soxhlet extractor for 6 hours. Finally, solvents were evaporated from the mixtures. Plant materials (10 g) were extracted in 100 mL of boiling water for 15 min before being filtered. Water extracts were lyophilized. All extracts were stored at 4°C until further analysis.

The total phenolic contents were determined using the Folin–Ciocalteu. The results were presented as gallic acid equivalents (mg GAEs/g dry extract) for the assays (Selamoglu et al., 2017).

Antioxidant assays were performed using methods that have been previously reported (Selamoglu et al., 2017). The antioxidant potential was calculated as follows: 2,2-diphenyl-1-picrylhydrazyl (DPPH), cupric-reducing antioxidant capacity (CUPRAC) mmol TE/g extract in the.

The studies were conducted in 3 parallels and the results were averaged.

## RESULTS AND DISCUSSION

The antioxidant activities of *A. kotschyana* extracts were evaluated using different assays. In our model, DPPH assays were used to assess radical quenching ability, while CUPRAC assays results indicated reducing power. This two test was useful to establish the total antioxidant capacity. The results are presented in Table 1.

**Table 1.** Results of biological activity

Species	Solvents	DPPH (%)	CUPRAC (mg TE/g)	Total Phenolic Content (mg GAE/g)
<i>A. kotschyana</i>	Ethanol	58.75±0.25	109.85±2.11	70.25±2.10
	Methanol	69.54±0.14	134.52±1.58	84±1.79
	Water	61.87±0.21	154.98±2.34	74±2.05

Values are reported as mean ± SD of three parallel experiments. TE: Trolox equivalent, GAE: Gallic acid equivalent

The findings showed that a correlation exist between DPPH and CUPRAC assays. Such a correlation was observed in another study (Bibi Sadeer et al., 2020). The methanolic and aqueous extracts exhibited the highest antioxidant activities in most of the assays, suggesting an important role of the phenolics of the extracts. The polarity-dependent increase in total antioxidant activity and reducing properties indicates that the extraction of strong antioxidant compounds is more favorable in polar solvents (Nawaz et al., 2020). Furthermore, in a

previous paper that highly polar solvents, such as methanol, can have a high effectiveness in the extraction of antioxidants (Altemimi et al., 2017), supporting our findings.

When the results were examined, the highest DPPH removal was observed in the extract in which methanol was used as solvent (69.54±0.14%). This result was followed by water extract (61.87±0.21%) and ethanol extract (58.75±0.25%). When the results of CUPRAC method were analyzed, the highest antioxidant property was observed in water extract (154.98±2.34 mg TE/g). In addition to these results, methanol extract (134.52±1.58 mg TE/g) and ethanol extract (109.85±2.11 mg TE/g) were found. It is known that antioxidant properties are related to phenolic substances in plant extracts. In this respect, the highest total phenolic content was obtained in methanol extract (84±1.79 mg GAE/g). This was followed by water extract (74±2.05 mg GAE/g) and ethanol extract (70.25±2.10 mg GAE/g).

As a result, differences in the biological activity of the extracts prepared with different solvents were observed. One of the reasons for these differences is the excess of biologically active compounds contained in the solvent. In addition, the ability of solvents to solubilize bioactive substances in plant samples varies with the solvent.

## CONCLUSION

In this study, the biological activities of *A. kotschyana* extracts were compared using different solvents. This is the first study to investigate the biological activity of extracts prepared using this plant. As a result of this study, it was determined that the extracts prepared using ethanol, methanol and water have biological activities. In addition, it was observed that phenolic substance content was obtained from 3 different solvents. This research presents valuable preliminary data on a member of *Arenaria* genus. However, further investigations such as in vivo bioavailability and toxicity studies need to be performed in the future, before projecting the plant for possible nutraceutical/functional food and/or pharmaceutical applications.

### Özet

Bebek ve çocukların bilişsel gelişimi, genetik ve çevresel faktörlerden etkilenmektedir. Bilişsel gelişimin sağlanmasında gebelik dönemi dahil olmak üzere yaşamın ilk yıllarında çocuğun yeterli ve dengeli beslenmesi önemlidir. Doğumdan sonra çocuğun kendisi için en ideal besin olan anne sütü ile beslenmesinin bilişsel gelişimi olumlu yönde etkilediği, öğrenme, anlamlandırma, neden-sonuç ilişkisi kurma, görsel ve işitsel hafıza, okuma-yazma ve matematik yetenekleri gibi alanlarda akranlarına göre zeka testi sonuçlarının daha iyi çıktığı bilinmektedir. Anne sütü içeriğinde bulunan birçok madde yenidoğanın beyin gelişimi ile ilişkilendirilmiştir. Bilişsel gelişim potansiyelinde yeterli ve dengeli beslenmenin olumlu etkilere sahip olduğu bilinmektedir. Bilişsel gelişim üzerinde etkisi bilinen beslenme ile ilgili pek çok faktör vardır ve bu faktörler her zaman yeterince açık değildir. Özellikle anne sütü ve bilişsel gelişim üzerine yapılan araştırmalar maternal IQ, sosyokültürel çevre gibi birçok karıştırıcı faktör olduğunu belirtmiştir. Bununla beraber, yeterli süre ve miktarda anne sütü alınmasının bilişsel gelişim üzerine ılımlı bir pozitif etkisi olabileceğinin altı çizilmiştir.

**Anahtar Kelimeler:** Anne Sütü, Emzirme, Laktasyon, Bilişsel gelişim, Beslenme.

### Cognitive development and lactation

### Abstract

The cognitive development of infants and children is affected by genetic and environmental factors. Adequate and balanced nutrition in the first years of life, including the pregnancy period, is prominent in ensuring cognitive development. After birth, the ideal food for infants is breast milk. It has a positive effect on cognitive development. The intelligence test results are better than his peers in areas; such as learning, meaningfulness, cause-effect relationship, visual and auditory memory, reading-writing, and math skills known to come out. Many substances contained in breast milk are associated with the brain development of the newborn. Adequate and balanced nutrition has positive effects on cognitive development potential. There are many nutritional factors known to have an impact on cognitive development. These factors are not always clear enough. Studies on breast milk and cognitive development have stated many confounding factors such as maternal IQ and sociocultural environment. However, adequate time and amount of breast milk intake may have a moderately positive effect on cognitive development.

**Key Words:** Breast milk, Breastfeeding, Lactation, Cognitive development, Nutrition

### GİRİŞ

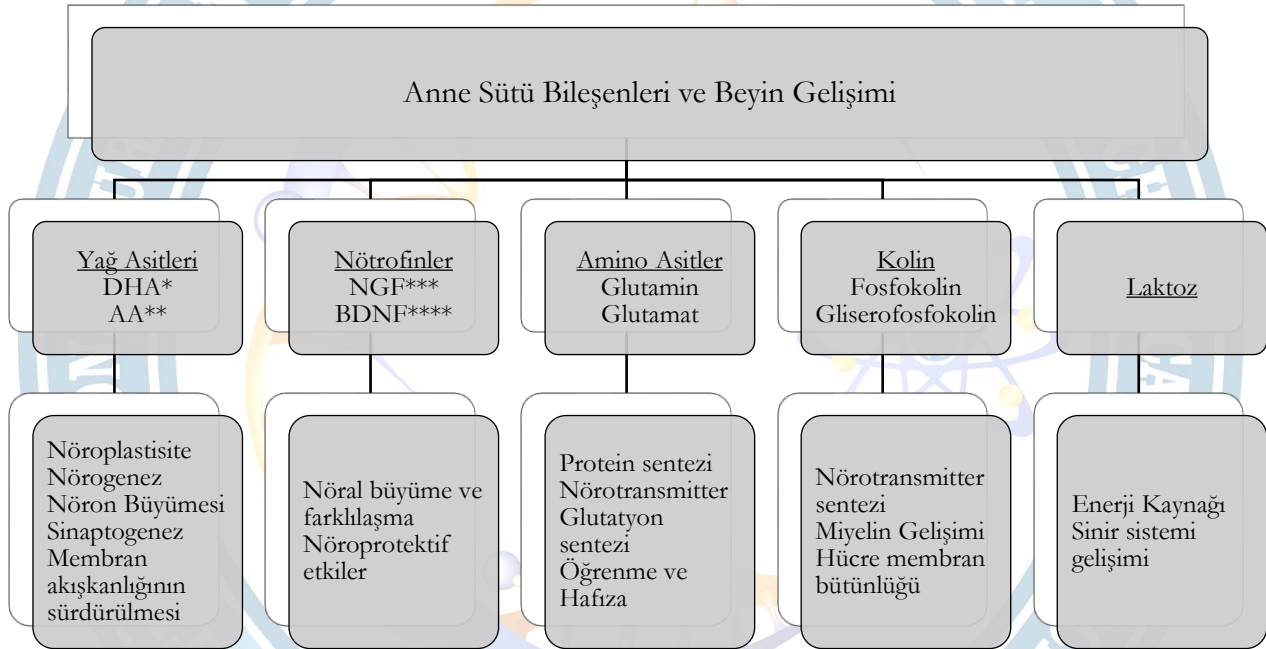

Anne sütü, bebekler için ideal besindir. Güvenli ve temizdir. Birçok yaygın çocukluk hastalığına karşı korunmaya yardımcı olan antikoklar içerir. Anne sütü, bebeğin yaşamının ilk aylarında ihtiyaç duyduğu tüm enerji ve besinleri sağlar. İlk yılın ikinci yarısında beslenme ihtiyacının yarısını veya daha fazlasını, yaşamın ikinci yılında ise üçte birine kadarını karşılamaya devam eder. Emzirilen çocuklar zeka testlerinde daha iyi performans gösterirler. Fazla kilolu veya obez olma olasılıkları daha düşüktür. Hayatlarının ilerleyen dönemlerinde diyabete daha az meyillidirler. Emziren kadınlarda ayrıca meme ve yumurtalık kanseri riski daha

düşüktür. Her beş bebekten üçü yaşamın ilk saatinde anne sütü alamıyor. 0-6 ay arası bebeklerin sadece %41'i sadece anne sütü alıyor. 0-23 ay arası optimal anne sütü alımı yapılırsa 820.000 çocuk kurtarılabilir. Anne sütü İkamelerinin uygunsuz pazarlanması, dünya çapında emzirme oranlarını ve süresini iyileştirme çabalarını baltalamaya devam ediyor. (Breastfeeding, WHO, 2020)

Dünya genelinde 12. ayda anne sütü alımı incelenmek için 1993-2013 yılları arasındaki raporlar araştırıldığında oranların gelişmiş ülkelere kıyasla gelişmekte olan ülkelerde daha yüksek olduğu görülüyor. Yine benzer şekilde düşük ve düşük-orta gelirli ailelere orta-yüksek ve yüksek gelirli ailelere göre, anne sütü alımı, ilk beş ay sadece anne sütü alımı, 12. ayda ve 23. ayda devam eden emzirme oranları daha yüksek bulunmuştur (Victora, ve ark., 2016).

## BİLİŞSEL GELİŞİM

Anne sütünün bilişsel gelişim üzerine etkileri ilk kez 1929 yılında araştırılmış ve pozitif yönlü etkinin altı çizilmiştir (Hoefler ve Hardy, 1929). Sonrasında bu konu üzerine birçok araştırma yapılmıştır. Zeka katsayısı (IQ) testleri üzerinde yoğunlaşan çalışmalar emzirme süresi ile testlerden alınan skorların arttığını işaret etmektedir (Horta ve ark., 2015). Anne sütü içeriğinde bulunan birçok madde yenidoğanın beyin gelişimi ile ilişkilendirilmiştir. Bu maddeler ve etki mekanizmaları şekil 1'de özetlenmiştir (Kamini ve ark., 2020).

Şekil 1. Anne Sütü Bileşenleri ve Beyin Gelişimine Etkileri

(\*Dokozaheksaenoik Asit, \*\*Araşidonik Asit, \*\*\*Sinir Büyüme Faktörü, \*\*\*\* Beyin Kaynaklı Nörotrofik Faktör)

Bir kesitsel çalışma ve 17 kohortun dahil edildiği bir meta analiz sonuçlarına göre, emzirme, zeka testlerinde artmış performans ile ilişkili bulunmuştur (+3.44 puan). Bu ilişki, maternal IQ ayarlandıktan sonra da devam etmektedir. Uzun vadeli takip çalışmaları, emzirmenin okul başarısını ve yetişkinlikteki geliri de etkilediğini işaret etmektedir (Horta ve ark., 2015). 2008-2009 yıllarında doğmuş 1752 çocuk dahil edildiği bir kohort çalışmasında anne sütü alımı ile iletişim, problem çözme, ifade becerisi ve hesap becerisinde anlamlı sonuç çıksa da anne IQ'su üzerinden düzenleme yapılmıca sadece problem çözme ve ifade becerisi anlamlı kalmıştır. Çalışma sonucunda bilişsel gelişim anlamında genetik ve sosyo-kültürel, sosyo-ekonomik durumun daha önemli olduğu, anne sütünün belirgin fark yaratmadığı gösterilmiştir (Kim, ve Choi, 2020). 2019'da yapılan anne sütü veya formülayla beslenen çocukların bilişsel gelişimlerinin değerlendirildiği sistematik derlemeye dahil edilen tüm çalışmalarda formülayla beslenen bebeklere göre anne sütü alanlar, anne sütü alanlar arasında ise daha uzun süre alanlar çeşitli testlerden daha yüksek bilişsel beceri skorları aldıkları tespit edilmiş ancak, düzeltici faktörler hesaba katıldıktan sonra sonuçlar anlamlı çıkmamıştır. Çalışma sonucu bilişsel gelişim açısından anne sütü/formüla ile anne sütü alım periyotundan ziyade maternal IQ, maternal eğitim seviyesi ve sosyoekonomik çerçeve en önemli faktörler olarak belirtilmiştir (Kim, 2019). Girard ve arkadaşları tarafından yapılan bir popülasyon kohort çalışmasına 2007-08 yıllarında doğan 11.134 çocuk dahil edilmiş ve dokuzuncu

ay ile üç ve beş yaşlarında değerlendirilmiş, veri kayıpları sonucu son sayı 7.478 kalmıştır. Çalışma diğer anne sütü – bilişsel gelişim çalışmalarında karıştırıcı faktörlerin göz ardı edildiğini öne sürmüştür. 13 alt ölçek açısından kohortu değerlendirdiklerinde tüm ölçeklerde anne sütünün pozitif etkisi gözlemlenmiş, karıştırıcı faktörlere göre düzenleme yapıldığında ise sadece 3. yaşta yapılan değerlendirmede bir faktörde (hiperaktivite) anlamlı sonuç kalmıştır (Girard ve ark., (2017). Couto ve arkadaşlarının 2020 yılında yayınladıkları ve 2015 – 2019 tarihleri arası yapılan sekiz çalışmanın analiz edildiği bütünlendirici derlemede öğrenme, anlamlandırma, neden-sonuç ilişkisi kurma, görsel ve işitsel hafıza, okuma-yazma ve matematik yetenekleri gibi alt ölçekler incelenmiştir. İlk altı ay sadece anne sütü alanlarda IQ, formüla alanlara göre bilişsel gelişim skorları anlamlı derecede daha yüksek (+8.9 puan) bulunmuştur (Couto ve ark., 2020).

Belarus’da yapılan Emzirmeyi Teşvik Müdahale Çalışması (PROBIT) adındaki randomize çalışmaya 31 doğum hastane ve polikliniği çalışmaya dahil edilmiş ve 96-97 yıllarında doğmuş totalde 17.046 anne-çocuk çiftinden 16.491’i 12 aylık süre ile takip edilmiştir. Hastanelerden 16’sı Dünya Sağlık Örgütü (DSÖ) ve Birleşmiş Milletler Çocuk Fonu girişimleriyle “Bebek Dostu Hastane” sıfatı ile müdahale, 15’i geleneksel hastane olarak kontrol grubu kabul edilmiştir. Müdahale grubunda ilk üç ay sadece anne sütü alanların oranı %43 iken kontrolde %6 bulunmuştur ( $p<0.001$ ). İlk altı ay sadece anne sütü alanların oranı ise sırasıyla %7.9 ve %0.6 ( $p<0.01$ ) olarak tespit edilmiştir (Kramer, ve ark., (2001). Probit çalışmasına katılanlardan 13.889’u 6.5 yaşında bilişsel gelişim bakımından değerlendirilmiş ve alt ölçekli IQ testleri ve öğretmen değerlendirmeleri incelenmiştir. Müdahale grubunda, kontrole kıyasla sözel IQ 7.5, performans IQ 2.9 ve total IQ 5.9 puan yüksek çıkmıştır. Müdahale grubunun öğretmen değerlendirmeleri de kontrole göre okuma-yazma becerilerinde anlamlı derecede yüksek bulunmuştur. Uzun süreli ve tek başına anne sütü verilmesi çocukların bilişsel gelişimini iyileştirir sonucuna varılmıştır (Kramer ve ark., 2008). Fakat uzun süreli ve tek başına anne sütü verilmesinin çocuk ve anne davranışları üzerinde risk veya faydasına dair kanıt bulunamamıştır. Bununla beraber müdahale grubunda olanların sonraki çocuklarını ilk üç ay sadece anne sütü ile beslemesi, kontrol grubuna göre iki kat daha olası bulunmuştur. Buradan da “Bebek Dostu Hastane” uygulamasının uzun dönemli pozitif etkilerinin de olduğu sonucuna varılmıştır (Kramer, ve ark., 2008). PROBIT çalışmaları term doğan sağlıklı bebekleri incelemiştir. 2017 yılında yayımlanan başka bir derleme ise PROBIT çalışmalarına ek olarak preterm doğumlarda anne sütünün etkisi ele alınmıştır. Hem term hem de preterm popülasyonlarda kanıtlar, emzirmenin veya anne sütü ile beslenmenin çocuk nörolojik gelişimine fayda sağladığına dair ikna edici bulunmuştur. Bu faydalar, formülaya kıyasla anne sütündeki besin öğeleri farklılıklarından kaynaklanabilir ve anne-bebek etkileşimindeki farklılıklar da işin içinde olabilir çıkarımı yapılmıştır. Genel olarak, nörolojik gelişimsel faydalara ilişkin mevcut kanıtlar, bebeklerin ilk altı ay boyunca sadece anne sütüyle beslenmesi ve hastaneye yatırılan preterm bebeklerin takviye edilmiş anne sütü alması gerektiğine dair mevcut önerileri desteklemektedir (Belfort, 2017).

Jing ve arkadaşları tarafından yapılan çalışmada 120 sağlıklı term çocuk, ilk altı ay anne sütü, süt bazlı formüla ve soya bazlı formüla ile beslenenler olarak üç gruba ayrılmış, her gruba 20 kız, 20 erkek çocuk dahil edilmiş ve üç, altı, dokuz ve 12. aylarda elektroensefalogram (EEG) ölçümlerine bakılmıştır. EEG aktivitesi ile miyelinizasyon hızlarına bakıldığında süt ve soya bazlı formüla ile beslenenler paralel özellik gösterirken anne sütü alanlar farklılık göstermiştir. Sonuçlara göre; formüla ile beslenenler anne sütü grubuna göre daha yüksek EEG aktivitesi görülmüş ve miyelinizasyon hızında sırasıyla altıncı ve dokuzuncu ay olmak üzere pik noktasına ulaşıldığı tespit edilmiştir. Yetişkinlik çağı nörolojik hastalıklar için geç pik noktasına ulaşmanın koruyucu olabileceği ifade edilmiştir (Jing ve ark., 2010).

Birleşik Krallıkta yapılan ve 2000 – 2001 yılları arasında, Birleşik Krallıkta doğan 11.544 çocuğun dahil edildiği “Millenium Cohort Study” adlı çalışma Koh tarafından analiz edilmiş, düşük test sonucuna sahip çocukların daha az emzirildiği ve bu test sonuçlarına göre 20. persentilden aşağı olanlar için anne sütünün etkisi, 80. persentilden yukarı olanlara göre iki kat fazla bulunmuştur. Emzirmeyi teşvik edici kamu politikalarının benimsenmesinin çocukların bilişsel gelişimindeki eşitsizliği azaltabileceği vurgulanmıştır (Koh, 2017).

Gibson ve Porter tarafından yapılan, emzirme döneminde maternal alkol ve sigara kullanımının çocuğun akademik başarısı ile ilişkisinin araştırıldığı çalışmaya 5.107 anne-çocuk çifti dahil edilmiş ve 2004’ten itibaren her iki yılda bir değerlendirmeye tabii tutulmuştur. Emzirme döneminde yüksek dozda alkol alan annelerin çocuklarında 7-10 yaş aralığında akademik başarıda düşüş gözlemlenmiştir. Sonuç olarak, laktasyon döneminde alkol tüketiminin doza bağlı olarak bilişsel gelişim ve akademik başarıyı olumsuz etkileyebileceği vurgulanmış, sigara tüketimi ile ilgili ise herhangi bir sonuca varılamamıştır (Gibson ve Porter, 2020).

## SONUÇ

Anne sütü çocuk gelişimi için en önemli besindir. Birçok araştırma ilk altı ay tek başına ve ardından iki yaşa kadar ek besinlerle alınan anne sütünün, çeşitli kronik hastalıklara karşı koruyucu olduğunu göstermektedir. Bilişsel gelişim konusunda da anne sütünün önemi çeşitli boyutlarda araştırılmıştır. Fakat zeka ve bilişsellik konularında etkisi tam olarak hesaplanamayan karıştırıcı faktörler vardır. (Maternal IQ, maternal eğitim seviyesi, sosyokültürel ortam vb.) Bu konuda bilimsel açıdan kanıt niteliği yüksek randomize kontrollü çalışmalar yapmak çoğunlukla etik dışı kabul edilmiştir. Bu sebeple bilişsel gelişim üzerine anne sütünün doğrudan etkisini saptamak zor olsa da literatür ılımlı pozitif etki olabileceğini işaret etmektedir.

#### Abstract

Mycosis fungoides (MF) is the most common type of Cutaneous T-cell lymphomas (CTCLs). These lymphomas constitute a collection of disorders identified by the existence of malignant clonal CD4+ T lymphocytes within the skin. Although extensive research is underway, the exact pathogenesis of MF still remains partially understood. miRNAs play a vital role in modulating various biological mechanisms related to immune cell function, cell proliferation, and the cancer cell progression processes. The aim of this study is to determine the expression levels of various miRNAs in the MJ mycosis fungoides cell line and compare them with dermal fibroblasts. MJ and BJ cells were cultured under suitable conditions, and RNA isolation was performed using Trizol. Following cDNA synthesis, the expression levels of various microRNAs were determined using Real-Time PCR. When compared to BJ cells, statistically significant downregulation of miR-146a, let-7e, miR-210, miR-424, miR-130a, and miR-200a, as well as upregulation of miR-155 and miR-21, were observed in MJ cells. In conclusion, the differences in miRNA expression levels in this MJ mycosis fungoides cell line will contribute to our understanding of which signalling mechanisms are activated in mycosis fungoides cells and their roles in cell proliferation, progression, and cancer pathways.

**Key Words:** Mycosis fungoides, miRNA expression, MJ cells

#### INTRODUCTION

The skin is the most common site of extranodal involvement in lymphoma after the gastrointestinal system. Cutaneous lymphomas are a heterogeneous neoplastic disease group originating from T and B cells, characterized by distinct histopathological, immunological, and clinical features (Willemze et al., 2019). While being the most common lymphoma type when compared to other cutaneous lymphomas, primary cutaneous T-cell lymphomas represent a group of diseases characterized by malignant clonal CD4+ T lymphocytes present in the skin (Keehn et al., 2007).

MF encompasses 60% of cutaneous T-cell lymphomas and 50% of all primary cutaneous lymphomas (Willemze et al., 2019). Clinically, MF is a chronic and slowly progressing disease, typically originating from CD4 (+) helper T cells and presenting in four stages: patch, plaque, tumor, and erythroderma. The prognosis can vary from long-term survival to rapidly progressing fatal outcomes (Kim-James and Heffernan, 2001). The molecular pathogenesis and biological mechanisms of MF have not been fully elucidated yet. Various immunological, genetic, and environmental hypotheses have been proposed; however, recent research has suggested the accepted hypothesis that uncontrolled proliferation of T cells, resistance developed against the apoptosis mechanism known as programmed cell death, and as a result, chronic cutaneous inflammation trigger the development of lymphoma (Min, 2018).

MicroRNAs (miRNAs), approximately 19-24 nucleotides in length, are small non-coding RNAs that function by base-pairing with complementary regions in target mRNAs, thereby suppressing translation or directly

leading to mRNA degradation (Bayraktar et al., 2019; Chen et al., 2013). They have been shown to play roles in many biological processes including development, differentiation, homeostasis, apoptosis, immune activation, signal transduction pathways, and cancer progression (Bartel, 2004). Recent research suggests that, in addition to the factors playing a role in the pathogenesis of CTCL, changes in miRNA expression may also be involved (Girardi et al., 2004; Ralfkiaer et al., 2014). Valencak and colleagues have reported that high DICER expression is a negative prognostic factor for CTCL (Valencak et al., 2011). Additionally, it has been noted that in CTCL, the expression of miR-155, miR-21, and miR-199/214 is upregulated, while miR-223 and miR-150 are downregulated. Some miRNAs may play roles in CTCL carcinogenesis by acting as oncogenic or tumor-suppressive factors, influencing cellular events such as proliferation, apoptosis, and invasion (Ralfkiaer et al., 2014; van Kester et al., 2011).

While there is a limited number of studies in the literature regarding miRNAs and their expression changes in CTCL, especially in the context of mycosis fungoides, determining miRNA changes between stages, and conducting comprehensive miRNA profiling studies involving both patients and MF cell lines can provide significant contributions to understanding the pathogenesis of MF (Ralfkiaer et al., 2014). The aim of the study is to determine the expression levels of certain miRNAs in a mycosis fungoides cell line, specifically the MJ cells, and to compare these levels with dermal fibroblast cells.

## MATERIALS AND METHODS

### Cell Culture

The study was conducted with the approval of the Pamukkale University Non-Interventional Clinical Research Ethics Committee, with the decision of the committee numbered 10 and dated 01.08.2017. In our study, the mycosis fungoides cell line "MJ (ATCC® CRL-8294™) ATCC® Number: CRL-8294" was commercially obtained. The BJ (ATCC® CRL-2522™) dermal fibroblast cell line was also used from our own stocks for the purpose of comparing the results obtained with MJ cells. The MJ cell line is a suspension-cultured T lymphocyte cell line characterized by CD2<sup>+</sup>; CD3<sup>+</sup>; CD4<sup>+</sup> characteristics and is commonly used as a cell culture model in mycosis fungoides research. The cell culture medium used in our study to sustain the cells' viability and for experiment tracking consists of DMEM supplemented with 1% Sodium Pyruvate, 2mM L-glutamine, 10% Fetal Bovine Serum (FBS), 1% non-essential amino acids, and 100 IU/ml penicillin. The cells were monitored for their growth, confluency status, and characteristics using an inverted microscope (Nikon, Japan). The cultures were maintained under appropriate conditions at 37°C with 95% humidity and 5% CO<sub>2</sub> in an incubator.

### RNA Isolation, cDNA synthesis and Real-Time PCR

Total RNA isolation from MJ and BJ cells was carried out using the Trizol method. RNA purity and concentration values were determined using Nanodrop. Subsequently, cDNA synthesis was performed using the miRNA cDNA Synthesis Kit with Poly(A) Polymerase Tailing (Abm, Canada) following the protocol provided by the manufacturer. Next, miRNA expression levels were determined using SYBR Green master mix (Eva Green) by StepOne Plus Real-Time PCR (Applied Biosystems). In our study, we investigated 13 miRNAs, namely hsa-miR-146a-5p, hsa-miR-375, hsa-miR-200a-3p, hsa-miR-223-3p, hsa-miR-224-5p, hsa-miR-155-5p, hsa-miR-21-5p, hsa-miR-214-3p, hsa-miR-424-5p, hsa-let-7e-5p, hsa-miR-130a-3p, hsa-miR-210-3p, and hsa-miR-204-5p. U6 was used as a housekeeping miRNA for normalization in our study.

### Statistical analysis

The  $\Delta\Delta\text{CT}$  method was used for the analysis of miRNA expression levels detected by RT-PCR. Changes in expression were determined using the web-based "RT<sup>2</sup> Profiler™ PCR Array Data Analysis" platform (<https://www.qiagen.com/tr/shop/genes-and-pathways/data-analysis-center-overview-page/>). Statistical analysis of the expression changes between the two groups was performed within this platform and analyzed using the Student t-test.  $p < 0.05$  was considered statistically significant.

## RESULTS AND DISCUSSION

According to the obtained results, when comparing the MF cell line MJ with BJ dermal fibroblast cells, statistically significant changes in miRNA expression were observed. In MJ cells, miR-21 showed a 1.27-fold increase, miR-155 exhibited a 1.6-fold increase, while miR-146a had a significant 12.3-fold increase. Additionally, let-7e showed a 7.3-fold increase, miR-210 had a 2.1-fold increase, miR-130a exhibited a 2-fold increase, and miR-200a had a 6.2-fold decrease ( $p < 0.05$ ). However, miR-204 expression did not show any significant change between the groups ( $p > 0.05$ ). In the MJ cell line group, miR-214 demonstrated a 5.4-fold increase, miR-223 showed a 2.6-fold increase, miR-224 had a 3.1-fold increase, whereas miR-424 exhibited an 11.5-fold increase, and miR-375 showed a substantial 20-fold decrease; however, these changes were not statistically significant ( $p > 0.05$ ). The results of the comparison for all miRNAs are demonstrated in Table 1.

Tale 1. Changes in miRNA expression levels when comparing MJ cell line with BJ

	miRNA	Fold regulation	p value (* $p < 0,05$ )
1	<i>miR-214</i>	5,4193	0,171957
2	<i>miR-223</i>	2,614	0,06719
3	<i>miR-21</i>	1,2763	0,000189*
4	<i>miR-146a</i>	-12,3464	0,00025*
5	<i>Let-7e</i>	-7,3415	0,0486*
6	<i>miR-155</i>	1,6753	0,00745*
7	<i>miR-210</i>	-2,1092	0,0473*
8	<i>miR-424</i>	-11,5525	0,65
9	<i>miR-204</i>	1,1124	0,056
10	<i>miR-130a</i>	-2,0848	0,00025*
11	<i>miR-224</i>	3,1171	0,32
12	<i>miR-375</i>	-20,6276	0,1
13	<i>miR-200a</i>	-6,2668	0,0036*

Recent studies have revealed the involvement of not only genes in signalling pathways but also non-coding RNA types, such as miRNAs, in CTCL pathogenesis. It has been shown that miRNAs play a critical role in the progression and pathophysiology of malignancies, and they are abnormally expressed in various cancer types. It has been suggested that miRNAs play a role in the pathogenesis of mycosis fungoides and may serve as a potential marker in MF patients (Lindahl et al., 2018; Ralfkiaer et al., 2011). In our study with MJ cells, we also investigated miR-155 expression, which we found to have a significant increase. In a recent study, they explored the role of miR-155 in vitro and in vivo in MyLa and MJ MF cell lines, Hut78 SS cell lines, a primary cell line derived from human peripheral blood lymphocytes as a control, and a xenograft animal model. It was observed that miR-155 expression was high in MyLA and MJ cells, while it exhibited lower expression in HuT 78 cells compared to the other cells. In the animal model study, it was demonstrated that silencing miR-155 reduced tumor tissue and development in vivo. Thus, it has been suggested that miR-155 could be an effective strategic target in MF pathogenesis and may be associated with fundamental cellular mechanisms related to cell survival (Moyal et al., 2017). While miR-223 expression was found to be increased in our study with the MJ cell line, McGirt and colleagues reported lower miR-223 expression in HuT-78 and HH cell lines when compared with CD+ T cells. Additionally, they noted that miR-223 regulates cell development, inhibits clonogenic potential, and targets proto-oncogenes such as E2F1, MEF2C, and TOX in these cell lines (McGirt et al., 2014). The initial results regarding other miRNAs in MJ cells have been presented in our study and added to the literature.

## CONCLUSION

In conclusion, considering the roles of miRNAs in cancer cells as both oncogenes and tumor suppressors, the detection of aberrantly expressed miRNAs can potentially play a role in the diagnosis and treatment of cancer. In dermatogenetic diseases such as mycosis fungoides, where the genetic and pathophysiological underlying

causes are not fully elucidated, the expression levels of these non-coding RNAs are important. The determination of miRNA expression levels investigated in our study will guide research into their potential as markers for treatment strategies that can be developed by targeting MJ cells.

## ACKNOWLEDGEMENTS

This study was produced from the PhD thesis of M.S. This study was supported by the Scientific Research Coordinatorship of Pamukkale University as the project numbered as 2018SABE004.

#### Abstract

Agrobacterium mediated transformation protocol were employed to Rio Grande tomato cultivar with few modifications to develop the transformants. Transformation efficiencies were evaluated by checking different parameters including plant regeneration efficiency, percent transformation efficacy, co-cultivation, co-infection times, concentrations of 6-benzylaminopurine (BAP) in regeneration selection media, gibberellic acid (GA<sub>3</sub>), and indole butyric acid (IBA) on shooting and rooting MS media. For tomato genetic transformation, *Agrobacterium tumefaciens* strain Eha-105 containing the desired gene was used. Eha-105 cells expressing the gene were streaked on LB plates with 50 mgL<sup>-1</sup> kanamycin and incubated at 28°C for 48 hours. Three different explants of various ages were selected for transformation including cotyledons, cotyledon nodes, and hypocotyl. The highest percent regeneration efficiency was found in 14 days old cotyledonary nodes (74.68%). Kanamycin concentration was standardized, and 50 mgL<sup>-1</sup> was shown to be optimal in terms of explant lethality. The highest percent regeneration efficiency was found for 48 hours of co-cultivation time (26.68%). The different concentrations of BAP in regeneration selection media significantly affected regeneration efficacy. Higher percent regeneration efficiency (15.82%) was observed at 1.5 mg L<sup>-1</sup> of BAP. The highest healthy shoot frequency was obtained at 0.2 mg L<sup>-1</sup> of GA<sub>3</sub>. The highest frequency (47.60%) of rooting was observed for media having 0.3 mg L<sup>-1</sup> of IBA concentration. Molecular analysis of T0 transgenic tomato plants revealed effective integration as well as increased relative expression of the gene. All these results indicated that an effective concentration of plant growth regulators is vital in the development of an efficient transformation Procedure for tomato transformation, ultimately leading to the establishment of improved tomato genotypes.

**Keywords:** Tomato, Rio Grande, IBA, BAP, Transformation.

#### INTRODUCTION

Tomato (*Solanum lycopersicum* L.) is an essential crop that is recognized for both its daily consumption and agricultural importance (Pozueta-Romero et al., 2001). The Rio Grande cultivar of tomato has received significant attention due to its distinctive traits and genetic potential. For improving the characteristics of this cultivar, such as resistance to biotic and abiotic stressors, gene characterization, and the production of useful proteins, genetic modification has emerged as an essential method (Goel et al., 2010; Khare et al., 2010). Utilizing the genetic potential of Rio Grande tomatoes requires the development of an effective and dependable transformation technique. Agrobacterium-mediated transformation stands out as a leading technique for establishing stable genetic variations because of its adaptability and applicability (McCormick et al., 1986). However, a robust methodology that can consistently produce transgenic plants with desirable features is necessary for a successful transformation.

In this work, we present a thorough investigation into the development and improvement of an Agrobacterium-mediated transformation strategy designed especially for the tomato cultivar Rio Grande. Our research focuses on the need for an approach that accelerates and simplifies the transformation process in order to overcome the difficulties experienced in genetic enhancement initiatives. We intend to build a methodology through a series of rigorous tests and studies that not only increases transformation efficiency but also decreases the time and resources needed for genetic modification (Velcheva et al., 2005).

The findings discussed in this study offer a promising tool for researchers and agriculturalists seeking to advance the genetics of Rio Grande tomatoes. By developing a consistent and robust transformation protocol, we contribute to the wider aim of harnessing the genetic capability of this cultivar, ultimately promoting tomato production and crop improvement efforts.

## **MATERIALS AND METHODS**

### **Growing of Tomato (cv. Rio Grande) Plants in Tissue Culture Conditions**

To grow Tomatoes (cv. Rio Grande), MS-0 nutrient medium was used to plant. Magenta growth boxes are used to grow the plants. Seeds were used for propagation and 9 seeds were grown in each growth box. Plants were grown at  $27 \pm 2^\circ\text{C}$  with a day length of 16 h light, provided by fluorescent tubes in the growth chamber.

#### **MSo Media Preparation**

MSo was prepared by adding 2.16 g of MS salt with vitamins. 15 g of sucrose was also added along with 8 g of plant agar. PH should maintain between 5.7-5.8. Seeds have been surfaced sterilized and placed on MS media.

#### **Seed Sterilization**

Seeds have been surfaced sterilized to avoid contamination before placing on MSo media by following the protocol. Firstly, rinse the seeds with autoclaved distilled water almost three times. Washed it with 75% ethanol almost 2 times. Rinsed it again with water. 20-30ml water and 1 ml sulcid have been added. Mixed it well and washed it 2-3 times. After that fungicides have been added and washed for 1 min. More water has been added to it and rinsed the fungicide has. 1 ml Tween-20 has been added and washed 3-5 times.

#### **Transfer of desired Gene to Tomato Plants**

A modified protocol for tomato transformation have been used by Muneeb et al., 2022. Cotyledon, cotyledon nodes, and hypocotyl explants of tomato cultivar were used for gene transfer when plants were uniformly sized 3-4 nodes. First of all, explants were transferred to Petri dishes containing sterile MSo liquid medium, and *A. tumefaciens* culture containing pFGC 5941 vector was added and inoculated for 15 minutes with gentle shaking. The inoculated explants were put on co-cultivation media and kept in an incubator chamber at  $28^\circ\text{C}$ , for 48 hrs.

#### **Co-Cultivation Media (CCM)**

Explants were washed with sterile distilled water and sulcid (Antibiotic) for 20 min after 48 hrs. The explants were then dried on sterile filter paper. The washing process was performed to remove all agrobacterium remaining on the explants. Then the explants were placed on co-cultivation media. The explants were kept in a growth chamber at  $24^\circ\text{C}$ , 16 hours light and 8 hours dark.

#### **Regeneration Selection Media (RSM)**

To obtain transgenic plants, RSM media was used. Phosphinothricin (PPT) was used for plant selection in gene transfer. Ph should be set to 5.75-5.85 approximately.

#### **Transfer and Selection on the Shoot Media (SEM)**

Approximately 25 days later, a shoot formed on the explants. Developed candidate transgenic shoots were then grown in shoot-induction MS media. Ph should be set to 5.75-5.85 approximately.

#### **Transfer and Selection Root Induction Media (RIM)**

Approximately 25 days later, shoots formed on the explants. Callus and developed candidate transgenic shoots were then grown in root-induction MS media. Ph should be set to 5.75-5.85 approximately.

#### **Confirmation of Transgenic Plants by Molecular Analyses**

The DNA was extracted from the leaves by the Cetyl trimethylammonium bromide (CTAB) extraction method (Doyle and Doyle, 1987) with a few modifications. The extracted DNA was stored at  $-20^\circ\text{C}$ .

#### **PCR Assays**

According to DNA quantity and quality results, all samples were diluted to a final concentration of 50ng/ $\mu\text{l}$ . The PCRs were carried out with 16.8  $\mu\text{l}$  sterilized water, 0.5  $\mu\text{l}$  of 10  $\mu\text{M}$  dNTP mix, 2  $\mu\text{l}$  of 25 mM  $\text{MgCl}_2$ , 2.5  $\mu\text{l}$  of 10X Taq buffer, and 0.5  $\mu\text{l}$  of 10  $\mu\text{M}$  of each primer with 0.20  $\mu\text{l}$  of 5 Unit/ $\mu\text{l}$  Taq DNA polymerase (Promega, Madison, WI, USA) and 2  $\mu\text{l}$  of pure DNA. The total final reaction mixture of PCR was 25  $\mu\text{l}$ . Reactions were incubated at  $94^\circ\text{C}$  for 2 min and following 40 amplification cycles (30 s at  $95^\circ\text{C}$ , 30 s at  $55^\circ\text{C}$ , and 30 s at  $72^\circ\text{C}$ ) were performed. The final PCR products were visualized under UV light after electrophoresis on ethidium bromide-stained 1.5% agarose gels.

**Table 2.** Effect of seedling age and explant type on percentage transformation efficiency of *Solanum lycopersicon* L. cv. Rio Grande.

Seedlings age (d)	Transformation efficiency (%)		
	Cotyledon leaf	Cotyledon nodes	Hypocotyl
7	15.38	13.79	14.29
14	13.24	17.31	14.71
21	12.90	14.89	13.64
28	8.33	8.70	6.67

### Placement of Explants on Co-Cultivation Media (CCM)

Later on, the inoculated explants were placed on co-cultivation media and kept in an incubator at 28°C, for 48 hours.

**Figure 3.** Placement of treated tomato explants on co-cultivation media (A, B, C)

The results indicated that there was a statistically significant co-cultivation time affecting the regeneration efficacy. The highest percent regeneration efficiency was found for 48 hours of co-cultivation time (26.68%) (Table 3).

**Table 3.** Effect of co-cultivation and co-infection times on percentage transformation efficiency of *Solanum lycopersicon* L. cv. Rio Grande.

Co-cultivation time (hr)	TE (%)	Co-infection time (min)	TE (%)
24	6.21 c	5	11.49 c
48	26.68 a	10	14.52 b
42	13.19 b	15	22.47 a
96	2.73 d	30	4.36 d
<b>LSD 0.05</b>	<b>0.96</b>	<b>LSD 0.05</b>	<b>1.69</b>

### Regeneration Selection Media (RSM)

After almost 48 hours of infection, explants were washed with sterile distilled water and sulcid for 15-20 min. The explants were then dried on sterile filter paper.

**Figure 5.** Placement of explants on RSM media containing PPT

### Shoot Induction Media (SIM)

Approximately after six weeks, shoots formation started on media plates containing PPT as a selection antibiotic.

**Figure 6.** (A,B,C) Shoots formation from hypocotyls, Cotyledon leaves and stems, (D) Shoot formation of explants treated with pfgc+clone construct, (E) Shoot formation of explants treated with pfgc empty construct, (F) Shoot formation of explants treated with pfgc+sense construct.

### Shoot Elongation Media (SEM)

Grown shoots were transferred to shoot elongation media containing ppt and sulcid as an antibacterial to avoid contamination.

**Figure 7.** Transfer of grown shoots to shoot elongation media

### Root Induction Media (RIM)

After 20-25 days on shoot induction media, plants were shifted to root induction media for root formation containing PPT and sulcid to avoid bacterial contamination.

**Figure 8.** Shifting of growing shoots on rooting media (A,B,C)

A higher percent regeneration efficiency (15.82%) was observed at 1.5 mg L<sup>-1</sup> of BAP. The highest healthy shoot frequency was obtained at 0.2 mg L<sup>-1</sup> of GA3. The highest frequency (47.60%) of rooting was observed for media having 0.3 mg L<sup>-1</sup> of IBA concentration (Table 4).

**Table 4.** Effect of different growth regulators used in plant regeneration media for calculating transformation efficacy

BAP (mg L <sup>-1</sup> )	Reg (%)	GA3 (mg L <sup>-1</sup> )	Shoot induction (%)	IBA (mg L <sup>-1</sup> )	Rooted shoots (%)
0.5	6.56 d	0.1	54.60 c	0.1	41.68 c
1.0	12.33 b	0.2	78.12 a	0.3	47.60a

<b>LSD<sub>0.05</sub></b>	<b>0.84</b>	<b>LSD<sub>0.05</sub></b>	<b>1.13</b>	<b>LSD<sub>0.05</sub></b>	<b>1.31</b>

### Confirmation of Transgenic Plants by Molecular Analyses

Genomic DNA was taken from tomato plants by using the CTAB method with few modifications. DNA was quantified both with nanodrop and gel electrophoresis for quantity and quality.

#### PCR Assays

Pure extracted DNA was used and tested by PCR. PCR was performed by BAR primers to confirm transgenic plants.

**Figure 9.** PCR assay for the confirmation of putative transgenic plants by BAR gene primers, Lane L: Gene Ruler 1kbp DNA Ladder (Thermo Scientific), + indicates positive control, - indicates negative control, Sample ranges from 1-22.

### DISCUSSION

We have effectively enhanced a transformation technique using agrobacterium for the Rio Grande tomato cultivar, by minor modifications to previously employed methods. These strategies has greatly improved transformation efficiency by methodically assessing critical transformation characteristics, such as plant genotype, explant type, and agrobacterium strain selection (Bakhsh et al., 2014; Cortina and Culiáez-Macià, 2004). The achievement of this goal is vital for the robust development of transgenic tomato lines with desired features, such as viral diseases, insect resistance or tolerance to unfavorable environmental conditions (Madhulatha et al., 2007). Additionally, our streamlined approach minimizes resources while also enhancing efficiency, making it affordable for use in both agricultural and research applications (Davis et al., 1991). Furthermore, this methodology's applicability to additional tomato cultivars broadens its application, enhancing breeding initiatives and genetic research involving a variety of tomato cultivars (Velcheva et al., 2005). This protocol enables scientists and breeders to more effectively integrate beneficial features into the Rio Grande cultivar, resulting in the growth of healthier and more robust tomato crops (Liu, 1999).

Future studies should concentrate on improving the methodology and investigating cutting-edge genetic methods, such as RNAi and CRISPR/Cas9-based genome editing, to increase the precision of genetic modification. As a result, our research represents an important step toward utilizing the genetic potential of the Rio Grande tomato cultivar, providing solutions to difficulties tomato growers encounter, and enhancing the security of the world's food supply.

### CONCLUSION

Through our research, an effective agrobacterium-mediated transformation strategy was created specifically for the Rio Grande tomato genotype under in vitro conditions was highlighted by the optimization of key limiting parameters. These results provide useful information for enhancing transformation techniques in different tomato cultivars. Our work provides a useful and affordable method for developing agricultural traits and enhancing tomato productivity and quality, which helps genetic improvement efforts in tomatoes overall for long term uses.

## ACKNOWLEDGEMENTS

The current research was produced by the Doctoral Thesis of Qurat ul Ain SAJID that was carried out at Niğde Ömer Halisdemir University Niğde, Turkey.

#### Abstract

The incredibly growing food consumption and demand in the world has confirmed the necessity of controlling food additives much more strictly. In Turkey, which is the country that consumes the most bread, lavash and phyllo per capita in the world, the analysis of the preservative content of these products is important for public health. Benzoic acid (BA), sorbic acid (SA), and their salts widely used preservatives for different types of foods inhibit proliferation of the microorganisms by interacting with the membranes, enzymes, proteins, and electron transport chain of the microorganisms. Although the use of BA and SA up to maximum limits do not affect health, excess consumption can cause some health problems such as metabolic acidosis, genotoxicity, convulsions, asthma, urticaria, and hyperpnoea. The main target of this study was to develop a sensitive, precise, and accurate headspace gas chromatography-mass spectrometry (HS-GC-MS) method with minimized chemical waste for determination of BA and sorbic acid SA in bread, lavash and phyllo samples. Esterification of the analytes and IS were conducted in HS vial during heating in HS oven. The validated method was successfully applied to the commercial samples. According to the results of the analyses, BA and SA were not detected except for one of the unbranded open products, while only SA was determined in the concentration range of 135 – 1412 mg/kg in all of the branded packaged products. This method, which was applied to real samples, is advantageous in terms of reducing toxic wastes to be used in routine analysis of BA and SA since it does not require large amounts of solvent as in the commonly used liquid chromatography methods.

**Keywords:** Preservative, food quality control, headspace gas chromatography, bread, lavash, phyllo.

#### INTRODUCTION

In every culture, people have tried to preserve foods in different ways since ancient times to prevent and delay changes that may occur in foods. Nowadays, with the increase in food production due to the increasing population in the world, the application of chemical preservatives has gained importance whereas people are correspondingly exposed to these chemicals. Benzoic acid (BA), sorbic acid (SA), and their salts widely used preservatives for different types of foods inhibit proliferation of the microorganisms by interacting with the membranes, enzymes, proteins, and electron transport chain of the microorganisms (Zengin et al. 2011; Hsu et al. 2014; Junqueira De Carvalho et al. 2016; Timofeeva et al. 2019; Bian et al. 2021; D'Amore et al. 2021; Feng et al. 2021; Pereira et al. 2021).

Although additions of BA and SA in the foods up to the maximum permitted concentration values of set by the regulatory agencies are accepted safe for health, excess consumption of the foods containing these preservatives can give rise to poisoning and health problems (Zengin et al. 2011; Hsu et al. 2014; Timofeeva et al. 2019; Bian et al. 2021; Feng et al. 2021; Pereira et al. 2021). Hence, proper controlling and monitoring of the preservatives in foods is crucial for food safety. In the rich cuisine of Türkiye, which ranks first in the world in per capita bread consumption, lavash and phyllo are also widely consumed. So, this work focused on measuring the concentration of BA and SA in bread, lavash, and phyllo samples.

Considering the importance of determination of BA and SA, it is a necessity to use a reliable analytical method. Many analytical methods have been reported for determination of BA and SA in food and beverage samples so far. Among them, high-performance liquid chromatography (HPLC) is the most common utilized technique (Techakriengkrai & Surakarnkul 2007; Zhao et al. 2012; Ozer et al. 2013; Ulca et al. 2013; Xu et al. 2013; Sugiura & Nakajima 2017; Iwakoshi et al. 2019; Timofeeva et al. 2019; Imanulkhan et al. 2020; Bian et al. 2021) Although HPLC is a widespread technique for simultaneous determination of BA and SA, it requires large amounts of toxic organic solvents in mobile phases and in sample pre-treatment processes. Also, some extraction pretreatments such as LLE, SPE, QuEChERS, and DLLME should be employed prior to chromatographic analyses due to eliminating the matrix interferences (Dong & Wang 2006; Techakriengkrai

& Surakarnkul 2007; Sugiura & Nakajima 2017; Iwakoshi et al. 2019; Bian et al. 2021; D'Amore et al. 2021). Furthermore, capillary zone electrophoresis (CZE) (Mato et al. 2006; Feng et al. 2021; Pereira et al. 2021), CE (Zhang et al. 2011; Hsu et al. 2014), capillary ion chromatography with conductivity detection (CIC-CD) (D'Amore et al. 2021), headspace solid-phase microextraction - gas chromatography - flame ionization detector (HS-SPME-GC-FID) (Dong & Wang 2006), thermal desorption gas chromatography mass spectrometry (TD-GC-MS) (Ochiai et al. 2002), GC-MS analysis after SPME (Sagandykova et al. 2017), and flow injection analysis – MS (FIA-MS) are the other developed methods published in the literature.

The main goal of this study was not only to adapt an HS-GC-MS method, which was previously developed for analysis of BA and SA in liquid beverages, to the solid bread, lavash and phyllo samples, but also to reduce amount of chemical waste. The static HS-GC systems are the gold standard for the analysis of volatile compounds since they commonly do not need complicated extraction procedures and provide highly reproducible and reliable results. Yet, BA and SA can not be analyzed directly by HS-GC-MS. Thus, BA, SA, and also salicylic acid (SaA) employed as internal standard (IS) were simultaneously derivatized to their volatile methyl esters with methanol in the vial under optimum HS conditions without applying any other pretreatment. This proposed method is a candidate to be used for routine analyzes in food control laboratories to protect public health.

## MATERIALS AND METHODS

### Chemicals

All reagents were of analytical reagent grade ( $\geq 99.0\%$ , Sigma-Aldrich). A New Human Power I Scholar UV system (Human Corporation, Seoul, Korea) was used for obtaining deionized water ( $\geq 18.2 \text{ M}\Omega \text{ cm}$  resistivity).

### HS-GC-MS System

A Perkin Elmer Clarus 500 GC equipped with an HS40 autosampler and a Clarus 500 Mass Spectrometer was used for the analyses. Chromatographic separations were carried out by utilizing a Stabilwax-DA GC column (30 m length, 0.25 mm i.d., and 0.5  $\mu\text{m}$  df.). The 22 mL HS vials containing the prepared solutions were kept in the HS oven at 140 °C for 15 min. The temperatures of the HS needle and the transfer line were 145 and 150 °C, respectively. The flow rate of the carrier gas was 1 mL/min. The temperature program of the GC oven was: I) 100 °C for 6 min; II) 20 °C/min to 220 °C; III) holding at 220 °C for 3 min. The temperature of the GC injection port was 250 °C. Total run time was 15 min. The SIR mode was utilized for quantification by selecting  $m/z$  67 for SA between 5.5 – 6.5 min,  $m/z$  105 for BA between 8.0 – 9.0 min, and  $m/z$  120 for SaA 9.5 – 10.5 min. At same time, TIC chromatogram was obtained by performing the full scan mode in the range of 15-250 amu for identifying the analytes.

### Sample Preparation

Firstly, 1-2 g of the representative pieces were collected from the samples purchased from the local bakeries, phyllo sellers, and supermarkets in Istanbul, Türkiye. After the samples were dried, they were finely grounded. 0.2 g of the grounded samples were transferred in to 10 mL of volumetric flasks. The samples were mixed and diluted with the solution of methanol:water 65:35 (v/v). It should be noted that the analytes and IS were derivatized to methyl esters since these organic acids could not be detected directly by HS-GC-MS. Optimal HS conditions for esterification reaction are mentioned above section. Therefore, 50  $\mu\text{L}$  of the filtered solutions, 50  $\mu\text{L}$  of the 10 mg/L of IS, and 200  $\mu\text{L}$  of 4.5 M sulfuric acid were mixed in the 22 mL HS vials. After the vials were tightly sealed with PTFE-lined rubber septum caps, they were loaded to the HS autosampler. The shaking option of HS oven was activated.

## RESULTS AND DISCUSSION

A static headspace GC-MS method of which parameters optimized in previous study (Destanoğlu 2023) for the analysis of BA and SA in non-alcoholic beverages was adapted to this work for determination of SA and BA in the different bread, lavash and phyllo samples. BA and SA were extracted from the samples using the solution containing 65:35 (v/v) methanol:water. Then, the esterification reaction took place in the presence of sulfuric acid/methanol in the 22 mL HS vial during heating in HS oven. GC oven temperature program and both MS modes were crucial for the selectivity and sensitivity of the method because the matrices of the samples different and they were diluted 50 times. Although the dilution factor was not very high, sensitivity became important since 50  $\mu\text{L}$  was taken for the vial.

## Analytical Figures

Retention time, linearity, limit of detection (LOD), and limit of quantification (LOQ) are summarized in Table 1.

**Table 1.** Analytical figures of the HS-GC-MS method

Parameter	Analyte	
	BA	SA
Retention time	8.4	5.9
Linear range (mg/L)	2.5 – 5000	12.5 – 5000
Regression equation	$y = 2.0602x - 0.4273$	$y = 0.2060x - 0.0258$
R <sup>2</sup>	0.9998	0.9998
LOD (mg/L)	1.5	4.5
LOQ (mg/L)	2.5	12.5

## Analysis of the Samples

The proposed method was applied to the bread, lavash and phyllo samples for determination of BA and SA. The results are given in Table 2. According to the Turkish Food Codex Regulation on food additives, SA can be added to the samples investigated this study up to 2000 mg/kg while the use of BA is not permitted (Turkish Food Codex 2013). When looking at the Table 2, all samples were suitable in terms of SA amounts, even SA was not detected in 1 commercial branded phyllo (no 4), 3 unbranded open phyllos (no 1,2,3,5), 2 commercial branded breads (no 1,2) and 2 local bakery breads (no 1,2). A SIR chromatogram of the commercial branded phyllo (no 3) is presented in Figure 1.

**Table 2.** HS-GC-MS analysis results of the bread, lavash and phyllo samples

Sample	SA (mg/kg)	BA (mg/kg)
commercial branded phyllo 1	146 ± 7	N.D.
commercial branded phyllo 2	192 ± 8	N.D.

## CONCLUSION

In this paper, BA and SA were investigated in 16 samples consisting of the bread, lavash and phyllo samples by utilizing a validated static Headspace-GC-MS method of which optimal parameters were developed previous study for beverage samples. The baked products could be analyzed directly with the HS-GC-MS, but by 50-fold dilution with the solution containing methanol that was employed as the alcohol for the in-vial derivatization reaction, the measurements were successfully carried out in the linear ranges. It was aimed also to consume the toxic chemicals comparing to the most common HPLC method. Thus, sensitivity became important since 50  $\mu$ L was taken for the 22 mL HS vial. The results showed that concentrations of BA and SA in all samples investigated in this study were suitable for the legal limits. Noteworthy, in terms of public health, it is an important issue that especially whether local producers use appropriate preservative content in a qualitative and quantitative manner must be strictly controlled. Therefore, it can be concluded that the proposed HS-GC-MS method is a candidate for routine analyses of the preservatives in the authorized laboratories.

#### Abstract

Algae is an important food source consumed by humans since ancient times. Macroalgae are classified into green, red, and brown algae. Brown algae, also known as Phaeophyta, comprises 20 classes; Phaeophyceae alone accounts for over 1800 species and 66% of the total algae consumption. Brown algae are a diverse group of marine organisms studied for their potential health benefits, including anti-inflammatory activities. These activities are often attributed to various bioactive compounds present in brown algae.

In this study, *Sargassum vulgare*, *Cystoseira tamariscifolia*, and *Padina pavonica* were collected in Mediterranean Sea, Türkiye. *n*-Hexane and 70% ethanol extracts of the plants were prepared by maceration method. The *in vitro* anti-inflammatory activity was evaluated by 5-lipoxygenase (5-LOX) inhibitory effect of the *n*-hexane and 70% ethanol extracts of brown algae spectrophotometrically. The anti-inflammatory activity of the *n*-hexane and ethanol extracts of *C. tamariscifolia* were determined as 60.33±4.4% and 67.58±1.5% in 130 µg/mL, respectively. The highest anti-inflammatory activity was observed in *C. tamariscifolia* extracts. The biological activity of *P. pavonica* extracts was also found to be more effective than *S. vulgare* extracts.

**Keywords:** Brown algae, anti-inflammatory activity, *Sargassum vulgare*, *Cystoseira tamariscifolia*, *Padina pavonica*

#### INTRODUCTION

Marine macroalgae, including seaweeds, have been recognized for centuries for their nutritional value and health benefits, particularly in Far Eastern countries such as Japan and Korea. Brown algae are the most consumed species, followed by red and green algae. Brown algae are rich in complex polysaccharides, minerals, proteins, vitamins, and phytochemicals, and have been associated with numerous health benefits, including cancer prevention, cholesterol reduction, and weight loss. Regular consumption of seafood, including seaweeds, has been linked to a longer life expectancy. As a result, there is growing interest in the production and consumption of high-value macroalgae-derived products in Western cultures (Lorenzo et al., 2017; Afonso et al., 2019).

Brown algae are also a rich source of bioactive compounds with excellent nutritional value, and are considered valuable food ingredients (Afonso et al., 2019; Li et al., 2021). Brown algae have been used for various purposes, including as a food source and traditional medicine. The brown algae are used in traditional practices for cancer, high cholesterol, thyroid disease and weight loss (Liu et al., 2012; André et al., 2021).

*Sargassum vulgare* is a brown algae species in temperate and tropical climates belonging to the Phaeophyceae family. These algae can be found primarily in shallow waters and coral reefs. Polyphenols, polysaccharides, phytohormones, carotenoids, vitamins, and unsaturated fatty acids are among the many important metabolites in *S. vulgare* (Marzban et al., 2022). The pharmacological activities of *S. vulgare* are found anticancer, anti-inflammatory, antibacterial and antiviral (Liu et al., 2012).

*Cystoseira tamariscifolia* has been shown to have antibacterial, antifungal, antiprotozoal, anti-inflammatory, antioxidant, and cytotoxic effects. These properties have been linked to the presence of many classes of compounds found in *C. tamariscifolia*, including phlorotannins (fucophloroethol, fucotriphloroethol, phlorofucofuroeckol, and bieckol) (Vizetto-Duarte et al., 2016; de Sousa et al., 2017).

*Padina pavonica* is a brown algae (Phaeophyceae) present worldwide and abundant along the Mediterranean and Atlantic coasts. *P. pavonica* extracts revealed many biological activities such as antimicrobial, anti-tumour, anti-osteoporotic, and anti-inflammatory (Abdelhamid et al., 2018; Drira et al., 2021).

In this research, *Sargassum vulgare*, *Cystoseira tamariscifolia*, and *Padina pavonica* were collected in Mediterranean Sea, Türkiye. *n*-Hexane and 70% ethanol extracts of the plants were prepared by maceration

method. The *in vitro* anti-inflammatory activity was evaluated by 5-lipoxygenase (5-LOX) inhibitory effect of the *n*-hexane and 70% ethanol extracts of brown algae spectrophotometrically. Anti-inflammatory activities of brown algae with different polarities were evaluated.

## MATERIALS AND METHODS

### Plant Material

The aerial parts of the brown algae were collected from Hatay, Türkiye, in 2020. The plant materials were diagnosed by Dr. Cemal Turan, and they were kept at the Herbarium of İstanbul Medipol University in İstanbul, Türkiye.

### Extraction Method

The aerial parts of three brown algae were dried in the shade, and the dry stems and leaves were crushed in a blender. The powdered plant materials were then extracted *n*-hexane (Sigma Aldrich) and ethanol (70%, v/v) (Sigma Aldrich) at room temperature for 24 hours.

Extracts were eventually filtered using filter paper after the maceration step was repeated three times. The combined filtrates were concentrated with a rotary evaporator (Buchi R300) to dryness under reduced pressure at 40°C. The dried extracts were kept at -20°C until they were tested for enzyme inhibition activity. The yields of obtained extracts are given in Table 1.

### Lipoxygenase (LOX) Enzyme Activity

Lipoxygenase (1.13.11.12, 7.9 Units/mg) enzyme activity inhibition levels were determined in a 96-well quartz plate, spectrophotometrically (Demirci et al., 2018). The experiments were carried out in 4 replicates, and the results are given in Table 2 as percent inhibition (%). Nordihydroguaiatic acid (NDGA) was used as a positive control.

$$\% \text{ Inhibition} = (E - S) / E \times 100$$

E: the absorbance of the enzyme without sample.

S: the absorbance of the enzyme with the test sample

### Statistical Analysis

The mean and standard deviation of data from *in vitro* enzyme inhibition was calculated (SD). The experiments were done in triplicates and all data were shown as mean  $\pm$  standard deviation (SD). GraphPad Software Prism 8 (San Diego, CA, USA) was used to determine the % inhibitory impact of the extracts and standard compounds based on the extracts dose-response curve.

## RESULTS and DISCUSSION

### 2.1. Yields of plant extracts

In the present work, the extracts were prepared from aerial parts of brown algae with maceration method. *n*-Hexane and ethanol were used for the extraction. The yields of the extracts were listed in Table 1. The yields of *n*-hexane extracts are lower than the ethanol extracts.

**Table 1.** Yields (%) of *n*-hexane and methanol extracts of brown algae

Plant	<i>n</i> -Hexane	70% Ethanol
<i>Sargassum vulgare</i>	0.54	12.35
<i>Cystoseira tamariscifolia</i>	0.87	8.94
<i>Padina pavonica</i>	0.63	12.12

## 2.2. Enzyme inhibition activity

The *in vitro* anti-inflammatory activity was evaluated by 5-lipoxygenase (5-LOX) inhibitory effect of the *n*-hexane and 70% ethanol extracts of brown algae spectrophotometrically. The anti-inflammatory activity of the *n*-hexane and ethanol extracts of *C. tamariscifolia* were determined as 60.33±4.4% and 67.58±1.5% in 130 µg/mL, respectively. The highest anti-inflammatory activity was observed in *C. tamariscifolia* extracts. The biological activity of *P. pavonica* extracts was also found to be more effective than *S. vulgare* extracts.

**Table 2.** Enzyme inhibition activities of brown algae (concentration: 130 µg/mL)

Plant	Solvent	Inhibitory activity against 5-LOX (percentage ± S.D. <sup>a</sup> )
<i>Sargassum vulgare</i>	<i>n</i> -Hexane	40.84±4.8
	70% Ethanol	32.75±3.8
<i>Cystoseira tamariscifolia</i>	<i>n</i> -Hexane	60.33±4.4
	70% Ethanol	67.58±1.5
<i>Padina pavonica</i>	<i>n</i> -Hexane	49.42±1.5
	70% Ethanol	45.55±5.7
NDGA		100±0.0

<sup>a</sup>: Standard deviation

Previous research looked at the phytochemical and medicinal properties of *Sargassum vulgare* collected from the Suez Canal. The anti-inflammatory profile of *S. vulgare* methanol extract was found that COX-1, COX-2, IL6, and TNF activity were 77.39, 88.35, 75.38, and 71.24%, respectively. The study on *S. vulgare* from the Suez Canal found that it contains saponins, known to produce anti-inflammatory effects (Shreadah et al., 2018). Also, phlorotannins, a compound found in *S. vulgare*, have been shown to have anti-inflammatory activity (Chouh et al., 2022).

A study found that methanol extracts from *Cystoseira tamariscifolia* and *C. nodicaulis* were inhibited inflammation (Custodio et al., 2016). According to a review article, the anti-inflammatory properties of the genus *Cystoseira* were mostly attributed to polyphenols and sulfated polysaccharides (Almurshedi et al., 2023). There is no specific study on the anti-inflammatory activity of *C. tamariscifolia*, but a closer look at this species as a source of anti-inflammatory activity was suggested (De La Fuente et al., 2020).

These studies suggest that *C. tamariscifolia* and related species may have anti-inflammatory activity, possibly due to polyphenols and sulphated polysaccharides. However, more research is needed to understand these compounds' mechanisms and potential applications fully.

A study found that the polyphenol-rich fraction from *Padina pavonica* exhibits significant anti-inflammatory activity (Alshaikheid et al., 2019). Another study suggested that the terpenoids-rich dichloromethane extract of *P. pavonia* may exert free radical-scavenging and anti-inflammatory activities (Germoush et al., 2020). While there is no specific study on the anti-inflammatory activity of *P. pavonica*, it has been found to have antimicrobial, antioxidant, and anticancer activities (Al-Enazi et al., 2018; Rushdi et al., 2021). These studies suggest that *P. pavonica* may have anti-inflammatory activity, possibly due to polyphenols and terpenoids. However, more research is needed to understand these compounds' mechanisms and potential applications fully.

## CONCLUSION

The brown algae consumption aligns with the increasing awareness of consumers' perceptions of organic and environmentally sustainable products. In this research, the brown algae were investigated anti-inflammatory activity. According to the results, the highest anti-inflammatory activity was observed in *C. tamariscifolia* ethanol extract. It is especially noteworthy that the efficacy in treating anti-inflammatories is exceptionally high. Therefore, *In vivo*, and clinical anti-inflammatory studies should proceed with the ethanol extract of *Cystoseira tamariscifolia* in the future.

#### Abstract

In this study we aimed to investigate the optical coherence tomography (OCT) images of healthy subjects for mean gray value (MGV), skewness and kurtosis, at retina and choroid in different regions. For this purpose, 200 OCT images of the 50 subjects (Female/Male is 1:1) retrospectively analyzed. Vertical and horizontal scans are processed for both retinal and choroidal region of interest (ROI) in a 6500  $\mu\text{m}$  area centered to fovea. Images have been binarized using Fiji/ImageJ and Niblack auto local thresholding method. MGV, skewness and kurtosis are measured for entire ROI, 65 parts at 100  $\mu\text{m}$  interval, and also for 3 vertical alignments as inner, middle and outer parts for these ROIs. For entire ROI retinal MGV is  $117.2 \pm 3.9$  and  $120.3 \pm 5.2$  ( $p < 0.001$ ) and choroidal MGV is  $76.3 \pm 6.8$  and  $78.5 \pm 6.7$  ( $p = 0.019$ ) for vertical and horizontal scans, respectively. Retinal skewness value is  $0.16 \pm 0.06$  and  $0.11 \pm 0.08$  ( $p < 0.001$ ) and choroidal skewness value is  $0.84 \pm 0.14$  and  $0.88 \pm 0.15$  ( $p = 0.024$ ) for vertical and horizontal scans for entire ROI, respectively. Retinal kurtosis value in entire ROI is  $-1.97 \pm 0.02$  and  $-1.98 \pm 0.02$  ( $p < 0.001$ ) and choroidal kurtosis value is  $-1.28 \pm 0.26$  and  $-1.20 \pm 0.29$  ( $p = 0.037$ ) for vertical and horizontal scans, respectively. Image processing techniques are gaining importance for differentiating the healthy and diseased one, as well as following up the disease progression. Thus, new methods, parameters and indexes could be a useful tool to investigate OCT images and define different properties of structures like retina and choroid. For retina and choroid; MGV, skewness and kurtosis were found to be significantly different in many vertical and horizontal scan regions and could be a candidate for image processing approaches.

## INTRODUCTION

The retina possesses a fundamental plan that encompasses many neuronal cell classes and exhibits conserved features in the design of the retinal structure and this characteristic allows for the possibility of conducting detailed analysis and making comparisons across different species (Hoon et al., 2014). In order to fulfill specific visual function requirements, it is possible for structural and functional retinal specializations to manifest in various species (Hoon et al., 2014).

The retina, which is situated at the innermost layer of the eye, is a neurosensory tissue that plays a pivotal role in the process of transforming incoming light stimuli into electrical signals that are subsequently capable of being processed and comprehended by the visual system, thereby allowing for the perception and interpretation of visual information (Gupta et al., 2016). The retina, which is located at the optic nerve surrounding, has a thickness of approximately 400  $\mu\text{m}$ ; however, as we move towards the ora serrata surrounding, the thickness decreases significantly to around 140  $\mu\text{m}$  (Gupta et al., 2016). These variations in thickness make the optic nerve surrounding the most thick part of the retina, while the ora serrata surrounding is the least thick part (Gupta et al., 2016). Furthermore, at the center of the retina lies the macular area, which is characterized by its circular shape with a radius of 1500  $\mu\text{m}$ . The macular area also exhibits a range in thickness, with values ranging from 350  $\mu\text{m}$  to 180  $\mu\text{m}$  (Gupta et al., 2016). The vertebrate retina is organized into cell layers with microcircuits working together to encode visual information, and the cellular and molecular mechanisms can shape the structure and function of the retina during development (Gupta et al., 2016; Hoon et al., 2014). The structure can be rearranged and function can be disrupted in retinal diseases, and there are studies that try to find approaches to re-establish the functional architecture of the retina. (Gupta et al., 2016; Hoon et al., 2014).

The choroid, a highly specialized vascular tissue responsible for the supply of essential nutrients and oxygen to the outer retina, fulfills a pivotal role in the ocular system (Nickla & Wallman, 2010). Not limited solely to its blood supply function, the choroid exhibits a many other responsibilities, including the regulation of thermal dynamics within the eye, the precise positioning of the delicate retina, and the secretion of crucial growth factors that contribute to the overall health and functioning of the ocular structures (Nickla & Wallman, 2010). This nature of the choroid underscores its significance in maintaining the integrity and optimal performance of the visual system (Nickla & Wallman, 2010). Alongside this multifunctional nature, the choroid, an essential component of the eye, is comprised of a diverse array of anatomical layers, each possessing its own unique characteristics and functions (Ferrara et al., 2016; Nickla & Wallman, 2010). These layers include the Haller's layer, Sattler's layer, Bruch Membrane, choriocapillaris and additionally, the suprachoroidea, the outermost layer of the choroid (Ferrara et al., 2016; Nickla & Wallman, 2010). Each of these layers, in their own distinct way, contribute to the overall structure and function of the choroid, highlighting the remarkable complexity and interconnectedness of the ocular system (Ferrara et al., 2016; Nickla & Wallman, 2010).

The comprehension of the cellular and molecular mechanisms that contribute to the formation and functioning of the retina's structure has been greatly enhanced by advancements in molecular tools, imaging techniques, and electrophysiological approaches and the development of such tools has facilitated the understanding of how the retina's structure and function are shaped (Hoon et al., 2014).

The functional significance of the retina and choroid for the fundamental disciplines such as biophysics, physiology, and histology is progressively advancing and a remarkable instrument, known as optical coherence tomography (OCT), has emerged, revolutionizing the imaging resolution of these anatomical components to a level that is comparable to histological quality (Bajwa et al., 2015; Murthy et al., 2016).

First described in 1991 at the Massachusetts Institute of Technology, this innovative technique employs the principles of low coherence interferometry (Huang et al., 1991). This methodology, which bears some resemblance to the ultrasonic pulse-echo equivalent, deviates from the traditional approach by utilizing near-infrared light beams (NIR) rather than sound waves (Huang et al., 1991).

OCT, an advanced diagnostic imaging technology employed in the field of ophthalmology, serves the purpose of evaluating the structures of the retina and optic disk (Bajwa et al., 2015). Due to its high precision and accuracy, OCT has gained significant recognition as an effective modality in the aforementioned domain (Bajwa et al., 2015). By employing OCT, clinicians are able to acquire comprehensive topographic information pertaining to the optic nerve head, the neuroretinal rim, and even the thickness of the nerve fiber layer (Bajwa

et al., 2015). As a result of its remarkable capabilities, OCT has emerged as a particularly valuable tool for the early detection of glaucoma and the continuous monitoring of patients who may be at risk of experiencing vision loss associated with this ocular condition (Bajwa et al., 2015). It is noteworthy that OCT is also capable of assessing a diverse range of ocular diseases, including but not limited to choroidal tumors, diabetic macular edema, age-related macular degeneration, central serous chorioretinopathy, and epiretinal membranes (Bajwa et al., 2015). Remarkably, OCT has demonstrated its utility in facilitating the management of various ocular inflammatory disorders (Bajwa et al., 2015). To augment its diagnostic capabilities, OCT can be effectively employed in conjunction with other imaging techniques such as wide-field retinal angiography and fundus autofluorescence, thereby enabling a comprehensive assessment of diverse ocular pathologies (Bajwa et al., 2015).

By the time, OCT gain more advance technology and spectral domain OCT (SD-OCT) became available with a higher resolution (Nassif et al., 2004). Enhanced depth imaging (EDI-OCT) technique gave SD-OCT with a higher resolution which particularly is important the evaluation of the choroidal part and choroidal diseases (Margolis & Spaide, 2009).

This higher resolution allowed researchers to perform more deepened and focused studies especially at the fields of image processing (Agrawal, Gupta, et al., 2016). Especially Niblack binarization method have been used to assess choroidal vascularity index (CVI) (Agrawal, Gupta, et al., 2016). Thus, the main aim of this study is to define choroidal and retinal mean gray value (MGV), skewness and kurtosis after binarization in vertical and horizontal OCT scans.

## MATERIALS AND METHODS

This study, which was conducted at the Department of Biophysics, Faculty of Medicine, Hacettepe University, aimed to provide a retrospective analysis of the optical coherence tomography image analysis findings and conducted in the context of a doctoral thesis. In order to achieve this, a total of 100 eyes from 50 subjects, comprising 25 females and 25 males, were included in the study. With vertical and horizontal scans there were a total of 200 OCT images. The data and information pertaining to each subject were collected from the Clinic of Ophthalmology, Ankara Training and Research Hospital, University of Health Sciences. Subjects who have applications to the Clinic of Ophthalmology, Ankara Training and Research Hospital, University of Health Sciences, in the three years prior to August 2017, and fall within the age range of 15 to 65, and have no previous record of ocular disease, systemic disease, or ocular surgery, and possess both conventional and computer-based archive data that can be accessed, and have SD-OCT and EDI-OCT images (Spectralis Heidelberg Engineering in Heidelberg, Germany), and have both vertical and horizontal images available, and possess SD-OCT images of sufficient quality for accurate interpretation, have been selected as meeting the inclusion criteria.

Both traditional archive systems within hospitals and digital archive systems were employed as tools for gathering data, in addition to the data collected from the SD-OCT device. In order to obtain a comprehensive understanding, various pieces of information were retrospectively collected and documented, including age, gender, demographic details, ocular disease history, systemic disease history, and history of ocular surgeries. All of the collected data were recorded within a sophisticated computerized database, ensuring accuracy and organization. To extract the SD-OCT images, the device's program was utilized. Through this program, the images were obtained and made accessible for further analysis and examination.

The images then were analyzed using the open-source image processing software Fiji/ImageJ (version 1.52d) (Schindelin et al., 2012; Schneider et al., 2012). The scale is set according to the image. Region of Interest (ROI) were delineated based on the horizontal scale, with a 6500  $\mu\text{m}$  area centered around the fovea. The borders of the retina and choroid was designated as internal limiting membrane, retinal pigment epithelium (RPE) layer and the choroidoscleral junction, respectively. 6500  $\mu\text{m}$  area is further divided to 65 horizontal and 3 vertical areas in order to compare the localized differences. Thus, calculations were performed for entire ROI, inner, middle and outer parts. In the binarization process images were converted to 8-bit and they were binarized using Niblack auto local threshold method (Agrawal, Gupta, et al., 2016). After binarization process retinal and choroidal MGV, skewness and kurtosis have been measured for vertical and horizontal scans. All the measurements were performed using a semi-automated method utilizing Fiji/ImageJ program (İnam, 2018).

The data were imported into SPSS 21.0 (IBM SPSS Statistics V21.0) and Microsoft Excel (Microsoft Excel for Mac V16.11) for statistical analysis and graphical demonstrations. Descriptive statistics were used to summarize the data, with qualitative variables presented as numbers and percentages, and quantitative variables summarized using mean, standard deviation, minimum, and maximum values. The normality of variables was assessed using the Shapiro-Wilk test, and Student's t-test or Mann-Whitney U test was applied depending on normal distribution. Statistical significance was determined using a p-value of less than 0.05. This study has obtained approval from the Hacettepe University Medical Faculty Non-Invasive Clinical Research Ethics Committee (11.07.2017, GO 17-670), and conducted as a doctoral thesis study, with no external resources or support sought and no conflicts of interest.

## RESULTS and DISCUSSION

There were 200 OCTs in this study with 100 horizontal and 100 vertical alignments for 2 eyes of the 50 cases (Female/Male ratio is 1:1). The age between female and male was not significantly different ( $40.71 \pm 15.08$ ,  $39.86 \pm 14.24$ ,  $p=0.838$ ).

In vertical scans mean retinal MGV value is  $117.2 \pm 3.9$  for entire ROI and  $120.3 \pm 5.2$  for horizontal scans ( $p<0.001$ ). For the inner parts, retinal MGV value is  $144.5 \pm 4.0$  for vertical scans and  $147.1 \pm 7.8$  for horizontal scans ( $p=0.003$ ). For the middle parts vertical retinal scans has a value of  $84.8 \pm 10.2$  and horizontal retinal scans  $82.0 \pm 9.3$  considering MGV ( $p=0.048$ ). For the outer parts, retinal MGV value was found to be  $124.8 \pm 11.9$  for vertical scans and  $133.6 \pm 11.5$  for horizontal scans ( $p<0.001$ ). In contrast, MGV in choroidal regions is more decreased when we look the general values. In vertical scans of entire ROI, choroidal MGV has a value of  $76.3 \pm 6.8$  and horizontal scans has a value of  $78.5 \pm 6.7$  ( $p=0.019$ ). For the inner parts, vertical scans have a value of mean choroidal MGV  $64.2 \pm 12.7$  and horizontal scans  $65.0 \pm 11.6$  which is found insignificantly different from each other ( $p=0.678$ ). For middle parts choroidal MGV in vertical scans has a value of  $86.8 \pm 10.4$  and in horizontal scans  $83.5 \pm 9.9$  ( $p=0.025$ ). For outer parts in vertical scans choroidal MGV is  $75.8 \pm 12.0$  and in horizontal scans  $85.1 \pm 10.9$  ( $p<0.001$ ). Thus, for retinal MGV there was a significant difference between vertical and horizontal scans for entire ROI, and inner, middle and outer parts as well. But for the choroidal MGV this difference is only significant for entire ROI, middle and outer parts. Inner regions of the choroid are seemed to be similar in terms of MGV between vertical and horizontal scan regions. All ROI is further investigated at  $100 \mu\text{m}$  apart for MGV and plotted graph can be seen in Figure 1A-B for retinal and choroidal measurements.

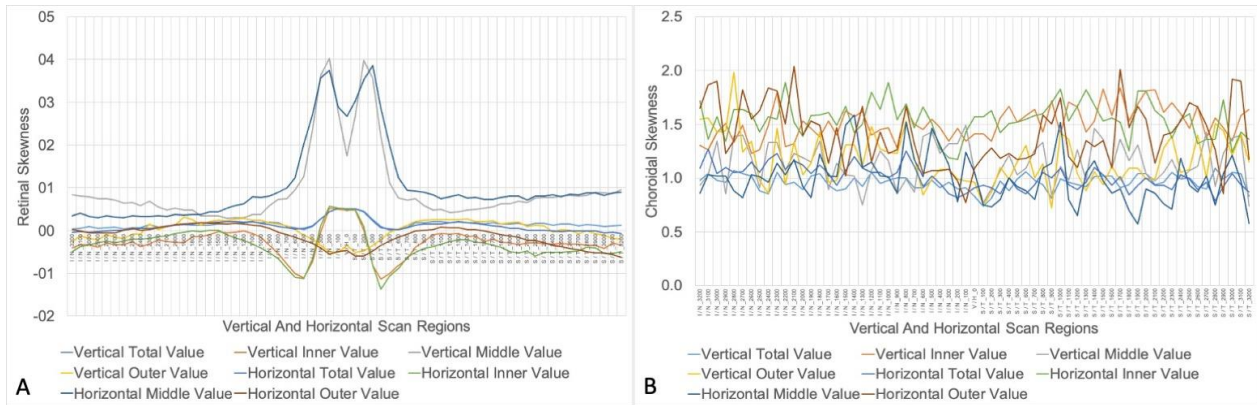

**Figure 1.** Retinal (A) and Choroidal (B) MGV for Vertical and Horizontal Scan Regions (MGV: Mean Gray Value)

Mean retinal skewness value for entire ROI in vertical scans is  $0.16 \pm 0.06$  and in horizontal scans  $0.11 \pm 0.08$  ( $p<0.001$ ). In the inner parts retinal skewness is  $-0.27 \pm 0.07$  for vertical scans and  $-0.31 \pm 0.13$  for horizontal scans ( $p=0.002$ ). Middle parts have a retinal skewness value of  $0.72 \pm 0.19$  for vertical scans and  $0.77 \pm 0.17$  for horizontal scans ( $p=0.047$ ) and outer parts have a retinal skewness value of  $0.04 \pm 0.19$  in vertical scans in comparison horizontal scans have a value of  $-0.10 \pm 0.18$  ( $p<0.001$ ). Mean choroidal skewness for entire ROI is  $0.84 \pm 0.14$  for vertical scans and  $0.88 \pm 0.15$  for horizontal scans ( $p=0.024$ ). For the inner parts choroidal skewness is  $1.15 \pm 0.29$  for vertical scans and  $1.18 \pm 0.37$  for horizontal scans which is found insignificantly

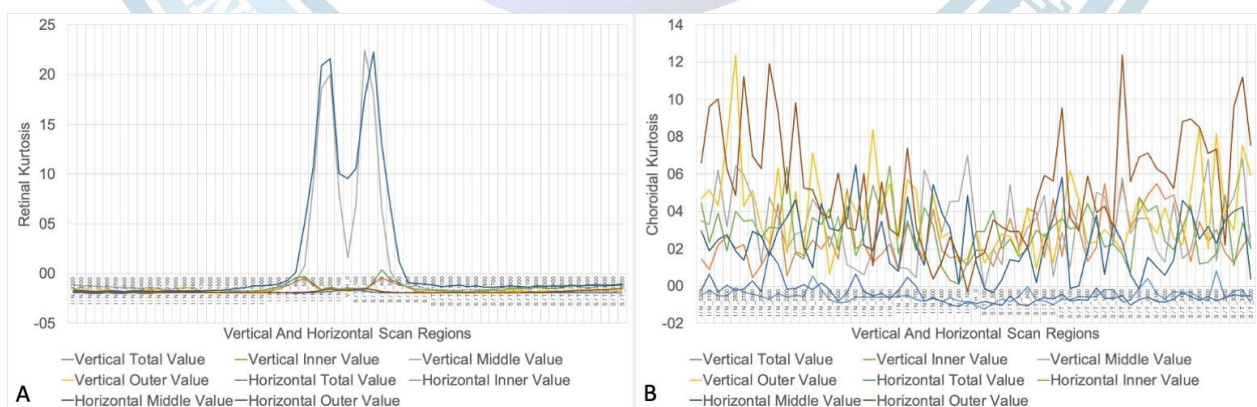

different from each other ( $p=0.530$ ). In the middle parts, choroidal skewness in vertical scans was found to be  $0.74 \pm 0.19$  and in horizontal scans  $0.68 \pm 0.20$  ( $p=0.033$ ). In the outer parts, choroidal skewness was  $0.72 \pm 0.21$  for vertical scans and  $0.90 \pm 0.25$  for horizontal scans ( $p<0.001$ ). For retinal skewness, there was a significant difference between vertical and horizontal scans at the entire ROI, inner, middle and outer regions; in contrast choroidal skewness is only significantly different at the entire ROI, middle and outer regions, not in the inner regions. For skewness, all ROI is further investigated at  $100 \mu\text{m}$  apart and plotted graphs for retinal and choroidal measurements which can be seen in Figure 2A-B.

**Figure 2.** Retinal (A) and Choroidal (B) Skewness for Vertical and Horizontal Scan Regions

Mean retinal kurtosis was found to be  $-1.97 \pm 0.02$  in vertical scans and  $-1.98 \pm 0.02$  in horizontal scans for entire ROI ( $p<0.001$ ). For the inner parts retinal kurtosis is  $-1.92 \pm 0.04$  for vertical scans and  $-1.89 \pm 0.08$  for horizontal scans ( $p<0.001$ ). In the middle parts retinal kurtosis is found to be  $-1.45 \pm 0.26$  for vertical scans and  $-1.38 \pm 0.25$  for horizontal scans ( $p=0.05$ ). Outer parts have a retinal kurtosis value of  $-1.96 \pm 0.11$  for vertical scans and horizontal scans have a retinal kurtosis value of  $-1.96 \pm 0.06$ , which there was not a significant difference between groups ( $p=0.777$ ). Mean choroidal kurtosis was found to be  $-1.28 \pm 0.26$  for the entire ROI in vertical scans and  $-1.20 \pm 0.29$  for horizontal scans ( $p=0.037$ ). For the inner parts choroidal kurtosis is found to be  $-0.59 \pm 0.73$  in vertical scans and  $-0.47 \pm 1.21$  in horizontal scans ( $p=0.395$ ). In the middle parts, vertical scans have a choroidal kurtosis value of  $-1.41 \pm 0.32$  and horizontal scans have a kurtosis value of  $-1.49 \pm 0.33$  ( $p=0.074$ ). For the outer parts, choroidal kurtosis was found to be  $-1.44 \pm 0.35$  for vertical scans and  $-1.12 \pm 0.49$  for horizontal scans ( $p<0.001$ ). When we compare retinal kurtosis for vertical and horizontal scans, only entire ROI and inner regions were found to be significantly different; in contrast choroidal kurtosis is different in entire ROI, middle and outer parts between vertical and horizontal scans. For kurtosis, all ROI is further investigated at  $100 \mu\text{m}$  interval and resulting graph can be seen in Figure 3A-B.

**Figure 3.** Retinal (A) and Choroidal (B) Kurtosis for Vertical and Horizontal Scan Regions

There are numerous studies in the literature aiming to find a better way to quantify OCT images and distinguish between healthy and diseased ones utilizing image processing techniques (Agrawal, Chhablani, et al., 2016; Agrawal, Li, et al., 2016; Agrawal, Salman, et al., 2016). Central serous chorioretinopathy have been

investigated for CVI and found to have higher CVI values considering their fellow eyes (Agrawal, Chhablani, et al., 2016). In another study CVI is measured alongside choroidal thickness in Vogt-Koyanagi-Harada disease, they both found to be significantly higher compared to the control group (Agrawal, Li, et al., 2016). Interestingly it is found that both choroidal thickness and CVI values are decreased significantly at follow up, compared to the baseline values (Agrawal, Li, et al., 2016). In a study conducted with panuveitis patients, at 3 months follow up, CVI change is found to be considerably decreased in uveitic eyes, and this decrease is found to be statistically significant compared with the control group change (Agrawal, Salman, et al., 2016). Even systemic diseases that have effects on eyes were investigated in terms of CVI and although there was not found a significant difference for retinal thickness, choroidal thickness, and many other parameters; CVI of the diabetes patients have been found significantly lower than the control group (Tan et al., 2016). These findings can show that even retinal and choroidal thickness measurements could be nonsignificantly changed, many other parameters and indexes obtained via image processing techniques could be more useful for demonstrating the difference between diseased and healthy ones. Another study has investigated that CVI and structural choroidal changes in age related macular degeneration and they have found that exudative age-related macular degeneration have significantly lower CVI values compared to fellow eyes, despite insignificant change in choroidal thickness (Wei et al., 2017). Thus, it is very important to investigate different parameters and indexes especially for healthy subjects. Different parameters and indexes could be useful for both differentiating the diseases and disease follow up.

## CONCLUSION

In conclusion, we investigated the retina and choroid, vertical and horizontal scans, in different regions for MGV, skewness and kurtosis at healthy subjects. We defined the mean values for different regions and found that there were localized differences between vertical and horizontal scans for these parameters. Further studies could be needed for investigating these parameters' role in different diseases.

#### Özet

Çeşitli mekanik özelliklere sahip olan poliimid malzemeler havacılık ve uzay teknolojisinde geniş bir kullanım potansiyeline sahiptir. Bu tür poliimid malzemelerden olan poliimid siloksan kopolimerlerin, bu çalışmayla güneş enerjisi teknolojisinde esnek altlıklar olarak kullanılmaya başlanılması hedeflendi. Random segment ve blok formda poliimid siloksan kopolimerler, Benzofenon-3, 3', 4, 4'-tetrakarboksilik dianhidrit (BTDA), 4, 4'-oksidianilin (ODA) ve bis (3-aminopropyl) polidimetilsiloksan (APPS) kullanılarak sentezlendi. ODA ve BTDA, Blok kopolimer yapıdaki sert segmentleri, APPS ve BTDA ise yumuşak segmentleri oluşturmaktadır. Yumuşak ve sert segment uzunlukları ayarlanarak bu kopolimerlerden pek çok çeşit üretilmektedir. Bu kopolimerler FT-IR analizi kullanılarak karakterize edildi. Random ve blok halde üretilen hibrit-nanokompozit poliimid siloksan kopolimer yapıların FT-IR sonuçlarında, Si-O-Si (asym Si-O-Si stretching) ve, Si-C (stretching) pikleri görüldü. FT-IR sonuçlarında elde edilen bu pikler, iki farklı biçimde üretilen her iki yapının da elastomer özelliğini doğrular yöndedir.

**Keywords:** Poliimid, poliimid siloksan, kopolimer.

#### GİRİŞ

Güneş pili teknolojisinde kullanılan ve araştırılan malzemeler üç gruba ayrılmaktadır:

- Kristal silisyum, çoğunlukla fotovoltaiklerde (PV) kullanılan ticari bir malzemedir.
- Fotovoltaik ince film hücreler geleneksel PV hücrelere göre daha ucuz olduğundan, üretim maliyetleri kristal silisyum güneş pillerine göre çok daha düşüktür.
- Üçüncü grupta çok eklemli yapılar yer almaktadır.

Bu çalışmayla, güneş pillerine esneklik fonksiyonu kazandırılarak kullanılabilirliğin artırılması ve ayrıca alt tabakadan kaynaklanan verim düşüklüğünün ortadan kaldırılarak esnek güneş pillerinin performansının artırılmasına katkı sağlanması amaçlandı.

Güneş pillerinin sol-jel yöntemiyle incelenmesinde kullanılacak esnek altlıklar 3 farklı türdedir. Bu esnek altlıklar:

- 1) Poliimid. Poliimid siloksanın özelliklerinde değişim yaratmak üzere, karşılaştırmalı olarak denenmiştir.
- 2) İnce esnek metalik yüzeyler. İnce esnek metalik altlıklar ile diğer esnek altlıklar üzerinde üretilen filmlerin yapışma ve elektriksel özellikleri arasındaki farklar karşılaştırmalı olarak incelenebilmektedir.
- 3) Bu çalışma kapsamında, esnek poliimid siloksan hibrit-nanokompozit polimer yapılar üretilmiştir. Bunun için, polidimetilsiloksan (PDMS) olarak kullanılan APPS ve poliimid sert ve yumuşak bloklar içeren blok kopolimerler oluşturuldu.

Polimer malzemelerde karşılaşılabilecek bazı olumsuzluklar; aynı zamanda kısaca "Tg" denilen, camsı geçiş değerlerinin düşük olması, düşük sıcaklıkta kullanımda direncin düşük olması, sıcaklık genleşme katsayısının (CTE) yüksek olması ve nem tutma oranlarının (WVTR) yüksek olması gibi durumlar, bu olumsuzluklar arasında sayılabilir.

Özellikle Tg oranlarının düşüklüğü en kritik olumsuzluktur. Çünkü, Tg değeri yarı iletken ince filmlerle kaplama üretmek için en önemli kriteri oluşturmaktadır.

Genel olarak çoğu yarı iletken malzemenin hibrit-nanokompozit yapılarla birlikte üretimi sırasında 200 °C civarında bir sıcaklık değerine ihtiyaç duyulur. Bu nedenle, poliimid malzemeler yüksek Tg oranlarına sahip olmaları nedeniyle en çok tercih edilen malzemeler arasında yer almaktadır.

Poliimid malzemelerin olumlu yönleri:

- Yüksek Tg değerlerine sahip oldukları için yarı iletken ince film ile her türlü hibrit yapıyı oluşturabilirler.
- Mükemmel sıcaklık stabilitesine sahiptirler.
- Hibrit oluşturma açısından, yüksek mekanik dayanıma sahiptirler.

Poliimidler, organik diaminlerden ve organik tetrakarboksilik asitlerden (veya bunların türevlerinden) elde edilen yüksek molekül ağırlıklı polimerlerdir.

Esnek altlıklar üzerinde, yarıiletken ince film üretebilmek için poliimidin, siloksan yapı ile hibritlenmesinin nedenleri şu şekilde sıralanabilir;

1) Poliimid yapıların termal genleşme katsayısını (CTE) ele aldığımızda, ısı yükselip camı geçiş sıcaklığını (Tg) geçtiğinde sıcaklığın arttığı gözlemlenmektedir (Friedrich et al., 2004). Bu durumun, yarıiletken ince film yapılar üzerinde deformasyonlara neden olabileceği düşünülmektedir.

2) Polidimetilsiloksan (PDMS) kaynağı olarak bis(c-aminopropil) polidimetilsiloksan (APPS) yardımıyla üretilen poli(imid siloksan) kopolimerlerinin Tg değerindeki herhangi bir artış, CTE değerinin istenilen düzeye getirilmesine neden olur (Pei et al., 2013).

PDMS kaynağı olarak APPS kullanılması durumunda, PDMS'nin CTE değeri ile altlık üzerinde üretilen ince filmin CTE değeri birbirine yaklaşabilmektedir.

Kopolimerizasyon, farklı kimyasal ve fiziksel özelliklere sahip iki yapının aynı polimer zincirine bağlanması sırasında amaçlanan özelliklere sahip yeni malzemelerin üretilmesini sağlayan en başarılı ve genel yöntemlerden biridir. Ayrıca, polisiloksan ve poliimid kombinasyonundan üretilen poliimid siloksan monomer blokları işlenebilirliği kolaylaştırmaktadır (Pei,X.; Chen,G.; Fang,X., Synthesis and Properties of Poly(imide siloxane) Block Copolymers with Different Block Lengths, J. APPL. POLYM. SCI. 2013).

Poliimid siloksan, yüksek esneklik ve yapışma özelliğine sahiptir ve her türlü agresif oksijen ortamında bozunmaya karşı dayanıklıdır. Bu nedenle bu çalışmanın içeriğinde esnek altlıkların incelenmesi için poliimid siloksan monomer blokları tercih edilmiştir.

Hibrit-nanokompozit polimer yapıların sentezinde kopolimerizasyon yöntemi kullanılmıştır. Kopolimerizasyon, farklı kimyasal ve fiziksel özelliklere sahip iki yapının aynı polimer zincirine bağlanması sırasında amaçlanan özelliklere sahip yeni malzemelerin üretilmesini sağlayan en başarılı yöntemlerden biridir. Ayrıca, polisiloksan ve poliimid kombinasyonundan üretilen poliimid siloksan monomer blokları işlenebilirliği kolaylaştırmaktadır (Pei,X.; Chen,G.; Fang,X., Synthesis and Properties of Poly(imide siloxane) Block Copolymers with Different Block Lengths, J. APPL. POLYM. SCI. 2013).

## **MALZEME VE METOD**

Bu çalışma kapsamında poliamik asit PDMS (polidimetil siloksan) içerisine, yumuşak bloklar eklenerek esnek poliimid siloksan kopolimerlerinin üretilmesi planlanmaktadır. Kimyasal malzemeler yüksek saflıkta Sigma Aldrich'ten temin edilmiştir.

Yüksek direnç özellikli poliimid siloksan random segment ve blok kopolimer sentezi, NMP (Metil-2-pirolidinon ve ODCB (oksidiklorobenzen)'den oluşan ortak çözücü ortamda sentezlendi. Sentezlenen, sert ve yumuşak bloklar karıştırıldı. Bu amaçla ODA ve BTDA sert bloklarının karıştırılmasıyla, APPS ve BTDA yumuşak bloklarının karıştırılmasıyla blok kopolimer zincirlerinin üretilmesi planlandı. Poliimid siloksan bloklar yüksek esneklik ve yapışma özelliğine sahip, agresif oksijen ortamında ayrışmaya karşı dayanıklı ve termal geçiş sıcaklığı yüksek olacak biçimde sentezlendi. Ayrıca, random segment poliimid siloksan görünür ışıkta optik olarak şeffaf olma özelliğine sahiptir.

Random segmentli poliimid siloksan hibrit-nanokompozit polimerik yapıların sentezi için, cam balon içerisine, azot ortamında, BTDA, NMP ve ODCB eklenerek, karıştırıldı. Dianhidrit tamamen çözüldükten sonra ODCB ile birlikte, APPS ve ODA sırayla ilave edilerek, 8 saat sürede 175°C'de karıştırıldı.

Poliimid siloksan hibrit-nanokompozit blok kopolimerlerin sentezlenmesi için, ODA ve BTDA poliimid sert bloğu oluştururken, APPS ve BTDA polisiloksan yumuşak bloğu oluşturacak biçimde sentez yapıldı. Cam flask içerisinde, azot ortamında, BTDA, NMP ve ODCB eklendi. Dianhidrit tamamen çözüldükten sonra ODCB ile birlikte, APPS yavaş yavaş cam flaska ilave edildi.

## TARTIŞMA

Üretilen, esnek altlıkların fiziksel özellikleri incelendi. Özellikle, fiziksel değişiklikler bağlamında, üretilen hibrit-nanokompozit polimerik yapılar incelendi ve değerlendirildi. Böylece esnek yüzeyler üzerine daha önce literatürde incelenmemiş, uzay teknolojisine uygun özgün bir çalışma hedeflendi.

Bu çalışma, iki adımdan oluşmaktadır: İlk olarak random segmentlere ayrılan hibrit-nanokompozit poliimid siloksan ve ardından poliimid siloksan blok kopolimerler, BTDA, APPS ve ODA kullanılarak, oda sıcaklığında azot ortamında, kondensasyon polimerizasyonu tekniği kullanılarak sentez edildi.

Random ve blok halde üretilen hibrit-nanokompozit poliimid siloksan kopolimer yapılar üzerinden gidilerek, yapının eldesinde kullanılan kimyasalların konsantrasyon oranlarında ki değişikliklerin, malzemenin yapısını nasıl etkilediği tesbit edilmeye çalışıldı. Konsantrasyon etkisini tesbiti amacıyla bu parametre üzerinde yapılan değişikliklerle, amid veya anhidrid kimyasal zincir halkalarının tamamlanarak kapandığını gösteren diamin-dianhidrid piklerinin tesbiti amacıyla FT-IR analizi yapılmıştır. Yapılan FT-IR analizi sonucunda bu pikler tesbit edilmiştir. Random ve blok halde üretilen hibrit-nanokompozit poliimid siloksan kopolimer yapıların FT-IR analizi Şekil 1 ve 2'de gösterilmiştir.

Random biçimde üretilen poliimid siloksan kopolimer yapının FTIR spektroskopi analiz sonuçlarında yapı, random pikler sergilemektedir. 2900-3100  $\text{cm}^{-1}$  arası alifatik C-H stretching, 1700-1800  $\text{cm}^{-1}$  arası asym C=O stretching, 1710-1720  $\text{cm}^{-1}$  arası sym C=O stretching, 1000-1100  $\text{cm}^{-1}$  arası asym Si-O-Si stretching, 1000-1010  $\text{cm}^{-1}$  arası sym Si-O-Si stretching, 750-790  $\text{cm}^{-1}$  arası Si-C stretching pikleri Şekil 1'de görülmektedir.

FTIR spektroskopisinde 1700-1800  $\text{cm}^{-1}$  arası ve 1710-1720  $\text{cm}^{-1}$  arası karbonil amid gruplarını ve 1500  $\text{cm}^{-1}$  lerde, amid yapının N-H bağları gözlenmektedir. Bu amid absorpsiyon pikleri 1700-1800  $\text{cm}^{-1}$  arasında –COOH karboksil halka zincirlerini tamamlayarak kapatmak üzere yok olmuştur. Bu da kopolimer yapının aromatik halka zincirlerinin tamamlanması ile oluştuğunu göstermektedir. Tüm kopolimer yapılarda 1700-1800  $\text{cm}^{-1}$  arası pikler imid grupları göstermektedir.

Şekil 1. Azot atmosfer ortamında random halde üretilen yüksek direnç özellikli hibrit-nanokompozit poliimid siloksan yapıların FTIR analiz sonuçları.

**Şekil 2.** Azot atmosfer ortamında blok halde üretilen yüksek direnç özellikli hibrit-nanokompozit poliimid siloksan yapıların FTIR analiz sonuçları.

Azot atmosfer ortamında blok halde üretilen hibrit-nanokompozit poliimid siloksan yapıların FTIR analiz sonuçları incelendiğinde ise,  $3425\text{ cm}^{-1}$  de  $-\text{OH}$  (hidroksil) pikleri,  $2956$  ve  $2879\text{ cm}^{-1}$  lerde alifatik C-H stretching düz zincir bağlar,  $1720$  ve  $1653\text{ cm}^{-1}$  de asym C=O stretching diamin pikleri,  $1544$ ,  $1499$ ,  $1475$ ,  $1444$ ,  $1426$ ,  $1404$ ,  $1301$  ve  $1225\text{ cm}^{-1}$  de aromatik halka zincirleri gösteren sym C=O stretching bağlar gözlenmektedir. Bu piklerden anhidrid yapının aromatik halka zincirin tamamlanması ile diamin piklerine dönüştüğünü anlıyoruz.  $1113$  ve  $831\text{ cm}^{-1}$  de asym Si-O-Si stretching, silikon pikler görülmektedir.  $655$ ,  $564$ ,  $507$  ve  $470\text{ cm}^{-1}$  de Si-C stretching pikleri görülmektedir.

Random biçimde üretilen poliimid siloksan kopolimer yapıda olduğu gibi,  $1720$ - $1650\text{ cm}^{-1}$  arası karbonil amid gruplarını ve  $1544$ ,  $1499\text{ cm}^{-1}$  lerde, amid yapının N-H bağları gözlenmektedir. Bu amid absorpsiyon pikleri  $1720$ - $1650\text{ cm}^{-1}$  arasında  $-\text{COOH}$  karboksil halka zincirlerini tamamlayarak kapatmak üzere yok olmuştur. Kopolimer yapı, aromatik halka zincirlerinin tamamlanması ile oluştuğu görülmektedir.

## SONUÇ

Poliimid blok kopolimer altlıklar, güneş pillerinde kullanılacak altlıklar olarak laboratuvar imkanları kullanılarak farklı esnek oranlarda üretildi. Böylece istenilen her formda, her konfigürasyonda, her ortamda kolaylıkla oluşturulabilen, erozyona dayanıklı alt tabakaların elde edilmesi mümkün olabilmektedir.

Bu çalışmanın sonuçları şu şekilde özetlenebilir:

- Esnek güneş pillerinde kullanılmak üzere poliimid siloksan polimer altlıkların üretilmesi ve yarı iletken kaplamalara uygunluğu incelenebilir.
- Literatür çalışmalarına göre poliimid siloksan hibrit polimerler, poliimidlere göre daha yüksek mekanik özelliklere ve cam geçiş sıcaklığı katsayısına sahiptir.
- Poliimid siloksanın bu özelliği sayesinde, güneş pillerinde kullanılan poliimidin özelliklerinin artırılarak esnek güneş pillerinin daha yüksek verimine katkıda bulunulması planlanmaktadır.
- Farklı kimyasal ve fiziksel özelliklere sahip iki yapının aynı polimer zinciri içerisinde birleştirilmesi olan kopolimerizasyon, amaçlanan özelliklere sahip yeni malzemeler üretmek için uygulanabilecek en başarılı ve genel yöntemlerden biridir.
- Ayrıca polisiloksan ve poliimid kombinasyonundan elde edilen poliimid siloksan monomer blokları, poliimidin işlenebilirliğini sağlar.
- Bu nedenle bu tez çalışması kapsamında poliimid siloksan esnek altlıkların incelenmesi tercih edilmiştir.

□ Random biçimde üretilen poliimid siloksan kopolimer yapının FTIR spektroskopi analiz sonuçlarında yapı, random pikler sergilemektedir. 2900-3100  $\text{cm}^{-1}$  arası alifatik C-H stretching , 1700-1800  $\text{cm}^{-1}$  arası asym C=O stretching, 1710-1720  $\text{cm}^{-1}$  arası sym C=O stretching, 1000-1100  $\text{cm}^{-1}$  arası asym Si-O-Si stretching, 1000-1010  $\text{cm}^{-1}$  arası sym Si-O-Si stretching, 750-790  $\text{cm}^{-1}$  arası Si-C stretching pikleri gözlenmiştir. FTIR spektroskopisinde 1700-1800  $\text{cm}^{-1}$  arası ve 1710-1720  $\text{cm}^{-1}$  arası karbonil amid gruplarını ve 1500  $\text{cm}^{-1}$  lerde, amid yapının N-H bağları gözlenmektedir. Bu amid absorpsiyon pikleri 1700-1800  $\text{cm}^{-1}$  arasında -COOH karboksil halka zincirlerini tamamlayarak kapatmak üzere yok olmuştur. Bu da kopolimer yapının aromatik halka zincirlerinin tamamlanması ile oluştuğunu göstermektedir. Tüm kopolimer yapılarda 1700-1800  $\text{cm}^{-1}$  arası pikler imid grupları göstermektedir.

□ Blok halde üretilen poliimid siloksan kopolimer yapının FTIR spektroskopi analiz sonuçlarında ise yapı, 3425  $\text{cm}^{-1}$  de -OH (hidroksil) pikleri, 2956 ve 2879  $\text{cm}^{-1}$  lerde alifatik C-H stretching düz zincir bağlar , 1720 ve 1653  $\text{cm}^{-1}$  de asym C=O stretching diamin pikleri, 1544, 1499, 1475, 1444, 1426, 1404, 1301 ve 1225  $\text{cm}^{-1}$  de aromatik halka zincirleri gösteren sym C=O stretching bağlar gözlenmektedir. Bu piklerden anhidrid yapının aromatik halka zincirinin tamamlanması ile diamin piklerine dönüştüğü anlaşılmaktadır. 1113 ve 831  $\text{cm}^{-1}$  de asym Si-O-Si stretching, silikon pikler görülmektedir. 655, 564, 507 ve 470  $\text{cm}^{-1}$  de Si-C stretching pikleri görülmektedir. Random biçimde üretilen poliimid siloksan kopolimer yapıda olduğu gibi, 1720-1650  $\text{cm}^{-1}$  arası karbonil amid grupları ve 1544, 1499  $\text{cm}^{-1}$  lerde, amid yapının N-H bağları görülmektedir. Bu amid absorpsiyon pikleri 1720-1650  $\text{cm}^{-1}$  arasında -COOH karboksil halka zincirlerini tamamlayarak kapatmak üzere yok olmaktadır. Kopolimer yapının, aromatik halka zincirlerinin tamamlanması ile oluştuğu görülmektedir.

## TEŞEKKÜRLER

#### Özet

Mesane fonksiyon bozukluğu, yaşlanmaya bağlı olarak çok sık görülen önemli sağlık sorunlarından birini oluşturmaktadır. Bu fonksiyon bozukluğu mesane detrusor kas kontraktilitesinin nöronal ve miyojenikkomponentlerinin modifikasyonu sonucu gelişmektedir. İnsan, sıçan ve fare mesane dokularında yapılan çalışmalarda yaşlanmaya bağlı detrusor kasında kolinerjik ve purinerjik yanıtların belirgin bir şekilde değiştiği ve mesane aktivitesindeki değişikliklerin bu farklılaşmadan kaynaklandığı ileri sürülmüştür. Hidrojen sülfür (H<sub>2</sub>S) memeli dokularında L-sistein' den enzimatik olarak sentez edilen bir gaz nörotransmitterdir. H<sub>2</sub>S'in sentezlendiği ve bu dokunun regülasyonunda rol oynadığı bildirilmiş ve ürogenital hastalıklar için önemli olabileceği ileri sürülmüştür. Ancak, mesane dokusunda yaşlanmaya bağlı L-sistein/H<sub>2</sub>S yolağı aktivitesinde oluşabilecek değişiklik ile ilgili bir çalışma mevcut değildir. Çalışmamızda yaşlanmaya bağlı detrusor kasındaki fonksiyonel değişikliklerde L-sistein/H<sub>2</sub>S yolağının olası rolünün araştırılması amaçlanmıştır. Çalışmamızda, izole fare mesane dokusunda kümülatif karbakol kasılma yanıtları değerlendirildi. Yaşlı ve genç kasılma yanıtlarında farklılık gözlemlendi. Kümülatif L-sistein gevşeme yanıtları genç ve yaşlı farelerden izole edilen dokularda karşılaştırıldı. Ayrıca, ekzojen H<sub>2</sub>S yanıtlarının araştırılması için kümülatif sodyum hidrojen sülfür gevşeme yanıtları da, genç ve yaşlı farelerden izole mesane prepatlarında araştırıldı. Endojen (L-sistein) ve ekzojen H<sub>2</sub>S (NaHS) gevşeme yanıtlarının yaşlı farelerde genç farelere farklılık gözlemlendi. Bu bulgular, mesane dokusunda yaşa bağlı olarak H<sub>2</sub>S yolağını etkilediğini düşündürmektedir.

**Anahtar Kelimeler:** fare, mesane, hidrojen sülfür

#### Role of the l-cysteine/hydrogen sulfide pathway in aging-related bladder dysfunction in mice

Bladder dysfunction is one of the most common health problems due to aging. This dysfunction develops as a result of modification of the neuronal and myogenic components of bladder detrusor muscle contractility. Studies conducted on human, rat, and mouse bladder tissues have suggested that cholinergic and purinergic responses in the detrusor muscle change significantly due to aging and that changes in bladder activity result from this differentiation. Hydrogen sulfide (H<sub>2</sub>S) is a gaseous neurotransmitter synthesized enzymatically from L-cysteine in mammalian tissues. It has been reported that H<sub>2</sub>S is synthesized and plays a role in the regulation of this tissue, and it has been suggested that it may be important for urogenital diseases. However, there is no study on the alterations of L-cysteine/H<sub>2</sub>S pathway activity due to aging in bladder tissue. In the present study we aimed to investigate the possible role of the L-cysteine/H<sub>2</sub>S pathway in functional changes in the detrusor muscle due to aging. In the present study, the cumulative carbachol contractions were evaluated in bladder strips isolated from aged and young mice. The contractile responses to the cumulative carbachol were markedly different in aged mice compared to young mice. Cumulative L-cysteine relaxation responses were evaluated in the bladder strips isolated from young and aged mice. Additionally, to investigate exogenous H<sub>2</sub>S responses, the cumulative sodium hydrogen sulfide relaxation responses were performed in isolated bladder preparations from young and aged mice. Differences in endogenous (L-cysteine) and exogenous H<sub>2</sub>S (NaHS) relaxation responses were observed in aged mice compared to young mice. These findings suggest that the alterations of H<sub>2</sub>S pathway may be occur in bladder tissue dependent to age.

**Keywords:** bladder, hydrogen sulfide, mice

## GİRİŞ

İdrarın depolanması detrusor kasının gevşemesi ve üriner sfinkterin kasılmasıyla; idrarın boşaltılması ise detrusor kasının kasılması ve üriner sfinkterin gevşemesi ile sağlanır (Coolsaet B, 1985; Geokas ve ark., 1985). Yaşlanma hemen hemen bütün fizyolojik sistemlerin aktivitesinde bir azalmaya neden olmaktadır (Diokno ve ark., 1992). Yaşlılarda, alt üriner sistem semptomlarının daha yaygın olduğu bilinmektedir (Brocklehurst ve Dillane, 1966). Mesanenin inervasyonunda kolinerjik, nitretrjik, peptiderjik sistemlerin rolü vardır. İnsan, sıçan ve fare mesane dokularında, yaşlanmaya bağlı innervasyondan sorumlu ilgili mekanizmalarda farklılaşmaların olduğu bildirilmiştir (Siroky MB, 2004). Yaşlı farelerden izole edilmiş detrusor kasında, mesane dolun, depolama ve boşaltım fonksiyonlarında hasar olduğu gözlemlenmiştir (Daly ve ark., 2014). Son çalışmalarda, yeni bir gaz nörotransmitter olan H<sub>2</sub>S 'in de mesane düz kasının regülasyonunda rol oynadığı gösterilmiştir (Fernandes ve ark., 2013). Yapılan araştırmalarda, H<sub>2</sub>S'in endojen olarak L-sistein 'den bu dokuda sentez edildiği ve L-sistein/H<sub>2</sub>S yolağının ürogenital hastalıkların tedavisine katkı sağlayabileceği belirtilmiştir (Fernandes ve ark., 2013a; Fernandes ve ark., 2013b; Patacchini ve ark., 2005). Ancak, mesane dokusunda yaşlanmaya bağlı L-sistein/H<sub>2</sub>S yolağı aktivitesinde oluşabilecek değişiklik ile ilgili bir çalışma mevcut değildir. Çalışmamızda yaşlanmaya bağlı detrusor kasındaki fonksiyonel değişikliklerde L-sistein/H<sub>2</sub>S yolağının olası rolünün araştırılması amaçlanmıştır.

## MATERYAL VE METOT

Çalışmalarda deney hayvanı olarak, Çukurova Üniversitesi Tıbbi Bilimler Deneysel Araştırma Merkezinden (DETAUM) temin edilen 25-35 gram ağırlıklarında swiss-albino genç (3-4 aylık) ve yaşlı (23-25 aylık) erkek fareler kullanıldı.

Çalışmada genç ve yaşlı fareler servikal dislokasyon ile öldürülerek, mesane detrusor dokuları izole edildi. İzole dokular, %95 O<sub>2</sub> ve %5 CO<sub>2</sub> ile gazlandırılan Krebs solüsyonu (mM: NaCl 118.1, KCl 4.7, CaCl<sub>2</sub> 2.5, MgCl<sub>2</sub> 6H<sub>2</sub>O 1.2, KH<sub>2</sub>PO<sub>4</sub> 1.2, NaHCO<sub>3</sub> 25, glucose 11.5) içeren 10 ml'lik organ banyolarına asıldı. Kas şeritleri 60 dakika boyunca inkübe edildi ve bu süre zarfında doku her 15 dakikada Krebs solüsyonu ile yıkandı. Kas uzunluğundaki değişiklikler izometrik bir dönüştürücü (MP35) aracılığıyla izometrik olarak kaydedildi.

Genç ve yaşlı farelerden izole edilen mesane şeritlerinin kasılma ve gevşeme yanıtları değerlendirildi. İlk deney grubunda, genç ve yaşlı fare gruplarından izole edilen idrar kesesi dokularında agonist kaynaklı kasılma yanıtları karşılaştırıldı. Şeritlerin kasılma kabiliyetini belirlemek için, izole edilmiş fare mesane şeritleri, 60 dakikalık dengeleme süresinden sonra 60 mM KCl ile önceden kastırıldı ve ardından dokular Krebs çözeltisiyle yıkandı ve 30 dakika boyunca yeniden dengelemeye bırakıldı. Bu süre sonunda kümülatif karbakol (10<sup>-4</sup>-10<sup>-8</sup> M) konsantrasyon-yanıt eğrisi elde edildi. Karbakol ile birinci seri kümülatif kasılma yanıtları elde edildikten sonra dokular 30 dakika dengelenmeye bırakıldı ve karbakol ile ikinci seri kümülatif konsantrasyon-cevap eğrisi elde edildi.

Diğer deney grubunda ise, endojen H<sub>2</sub>S'ye karşı gevşetici yanıtları değerlendirmek için mesane şeritleri karbakol (3x10<sup>-6</sup> M) ile önceden kastırıldı. Elde edilen kasılmadan sonra endojen H<sub>2</sub>S substratı olarak kümülatif L-sistein (10<sup>-6</sup>-10<sup>-2</sup> M) uygulandı. Birinci seri gevşetici yanıtlar alındıktan sonra dokular 30 dakika inkübe edildi ve ikinci seri gevşemeler aynı şekilde kaydedildi.

Ayrıca genç ve yaşlı farelerden izole edilmiş mesane dokularında ekzojen H<sub>2</sub>S'ye verilen gevşetici tepkilerin değerlendirilmesi incelendi. Bu amaçla KCl (60 mM) sonrası kasılmalar elde edildi ve dokular yıkandı. 30 dakikalık inkübasyon süresinin ardından mesane şeritleri karbakol (3x10<sup>-6</sup> M) ile önceden kastırıldı. Kararlı kasılmalar elde edildikten sonra ekzojen H<sub>2</sub>S olarak kümülatif NaHS (10<sup>-6</sup>-3x10<sup>-3</sup> M) uygulandı. Birinci seri gevşetici yanıtlar alındıktan sonra dokular 30 dakika inkübe edildi ve ikinci seri gevşemeler aynı şekilde kaydedildi.

İstatistiksel karşılaştırmalar için ikinci seri kasılmalar ve gevşemeler değerlendirildi. Tüm veriler ortalama ± S.E.M olarak sunulmuştur. Dokular arasındaki sonuçlardaki farklılıklar, tek yönlü varyans analizi ve çoklu karşılaştırmalar için düzeltilmiş eşleştirilmemiş t testi (Bonferroni düzeltmeleri) ile test edildi. 0,05'in altındaki P değerleri anlamlı kabul edildi.

## BULGULAR ve TARTIŞMA

### 1. Yaşlanmanın karbakol kasılmaları üzerine etkisi

Yaşlanmanın karbakol kasılmaları üzerindeki etkisini araştırmak için genç ve yaşlı farelerde karbakolün kasılma yanıtları incelendi. Genç (3-4 aylık) ve yaşlı (23-25 aylık) farelerden izole edilen mesane şeritlerine spesifik M3-muskarinik reseptör agonisti karbakol kümülatif uygulanarak ( $10^{-8}$ - $10^{-4}$  M) dokularda konsantrasyona bağlı kasılma yanıtları elde edildi. Karbakol'e verilen kasılma yanıtları, yaşlı (23-25 aylık) farelerde genç (3-4 aylık) farelere göre istatistiksel olarak anlamlı bir şekilde arttı ( $P<0.05$ ; Şekil 1;  $n=5$ ).

**Şekil 1:** Genç (3-4 aylık) ve yaşlı (23-25 aylık) farelerden izole edilen mesane şeritlerinde kümülatif karbakol ( $10^{-8}$ - $10^{-4}$  M) kasılma yanıtları. Karbakol kasılma yanıtları 60 mM KCl'nin yüzdesi olarak ifade edildi. \* genç fare grubuna göre anlamlılığı göstermektedir ( $P<0.05$ ). Veriler ortalama  $\pm$  SH olarak ifade edildi ( $n=5$ ).

### 2. Yaşlanmanın H<sub>2</sub>S sülfür gevşemeleri üzerine etkisi

Yaşlanmanın endojen H<sub>2</sub>S gevşemeleri üzerindeki etkisini araştırmak için genç ve yaşlı farelerde endojen H<sub>2</sub>S substratı L-sisteinin gevşeme yanıtları incelendi. Genç (3-4 aylık) ve yaşlı (23-25 aylık) farelerden izole edilen mesane şeritlerinde karbakol  $10^{-6}$  M ile kastırılmış dokulara kümülatif L-sistein ( $10^{-6}$ - $10^{-2}$  M) uygulanması doza-bağlı gevşemeye neden oldu. L-sistein gevşeme yanıtları yaşlı (23-25 aylık) farelerde genç (3-4 aylık) farelere göre istatistiksel olarak anlamlı bir şekilde azaldı ( $P<0.05$ ; Şekil 2;  $n=5$ ).

**Şekil 2:** Genç (3-4 aylık) ve yaşlı (23-25 aylık) farelerden izole edilen mesane şeritlerinde kümülatif L-sistein ( $10^{-6}$ - $10^{-2}$  M) yanıtlarının grafiği. \* genç fare grubuna göre anlamlılığı göstermektedir ( $P<0.05$ ). Veriler ortalama  $\pm$  SH olarak ifade edildi ( $n=5$ ).

Ayrıca, yaşlanmanın eksojen H<sub>2</sub>S gevşemeleri üzerindeki etkisini araştırmak için genç ve yaşlı farelerde eksojen H<sub>2</sub>S prekürsörü NaHS gevşeme yanıtları incelendi. Genç (3-4 aylık) ve yaşlı (23-25 aylık) farelerden izole edilen mesane şeritlerinde karbakol  $10^{-6}$  M ile kastırılmış dokulara kümülatif NaHS ( $10^{-6}$ - $10^{-3}$  M) uygulandı. Kümülatif NaHS ( $10^{-6}$ - $10^{-3}$  M) uygulanması doza-bağlı gevşemeye neden oldu. NaHS gevşeme yanıtları yaşlı (23-25 aylık) farelerde genç (3-4 aylık) farelere göre istatistiksel olarak anlamlı bir şekilde azaldı ( $P<0.05$ ; Şekil 3;  $n=5$ ).

**Şekil 3.** Genç (3-4 aylık) ve yaşlı (23-25 aylık) farelerden izole edilen mesane şeritlerinde kümülatif NaHS (10-6-10-3 M) gevşeme yanıtlarının grafiği. \* genç fare grubuna göre anlamlılığı göstermektedir (P<0.05). Veriler ortalama  $\pm$  SH olarak ifade edildi (n=5).

## SONUÇ

Sonuç olarak, yaşlı fare mesane düz kasında karbakol kasılmalarının genç fare grubuna göre artış göstermesi, mesaneden salınan endojen gevşetici maddelerin yaşlanmaya bağlı olarak azalmış olabileceğini düşündürmektedir. Ayrıca, yaşlanmaya bağlı olarak ürotelyumun hasar görmesi olasılığı da söz konusu olabilir. Endojen (L-sistein) ve ekzojen H<sub>2</sub>S (NaHS) gevşeme yanıtlarının yaşlı farelerde genç farelere göre azalmış olması ise yaşlanmanın H<sub>2</sub>S yolağını olumsuz olarak etkilediğini göstermektedir.

## TEŞEKKÜR

Bu çalışma, “TAY-2019-11963” kodlu proje kapsamında Çukurova Üniversitesi Bilimsel Araştırma Proje Birimi tarafından desteklenmiştir.

#### Özet

Bu çalışmada, ilk kaydı Erciyes Dağı'ndan verilen akrokarp karayosunu *Tortula lingulata* Lindb., Türkiye'den ikinci kez kaydedilmiştir. Avrupa'da nadir olan tür, bir deprem kırığı oluşumu olan Koramaz Vadisi'ndeki (Kayseri), Ağırnas yeraltı şehrinin girişindeki kumtaşı duvar üzerinden toplanmıştır. Avrupa IUCN Kırmızı Listesinde VU (hassas) kategorisinde değerlendirilen *Tortula lingulata*'nın morfolojik karakterleri fotoğraflarıyla birlikte verilmiş, ekolojisi ve Türkiye'deki yayılışı detaylı olarak anlatılmıştır.

**Anahtar Kelimeler:** Akrokarp, Briyofit, Koramaz Vadisi, Türkiye

### The second record of *Tortula lingulata* Lindb. (Bryophyta) from Türkiye

#### Abstract

In this study, the acrocarpous moss *Tortula lingulata* Lindb., first recorded from Erciyes Mountain, was recorded for the second time from Türkiye. The species, which is rare in Europe, was collected from the sandstone wall at the entrance of the Ağırnas underground city in the Koramaz Valley (Kayseri), which is an earthquake fracture formation. The morphological characters of *Tortula lingulata*, which is evaluated in the VU (vulnerable) category in the European IUCN Red List, are given with photographs, and its ecology and distribution in Türkiye are explained in detail.

**Keywords:** Acrocarpous, Bryophyte, Koramaz Valley, Türkiye

#### GİRİŞ

Briyofitler yaklaşık 15.000-25.000 tür ile dünyada Magnoliophyta'dan (~350 000 tür) sonra ikinci en büyük bitki grubudur. Yeryüzünde kutuplardan ekvatora suyun ve nemin var olduğu hemen her yerde yaşayabilirler (Glime, 2017).

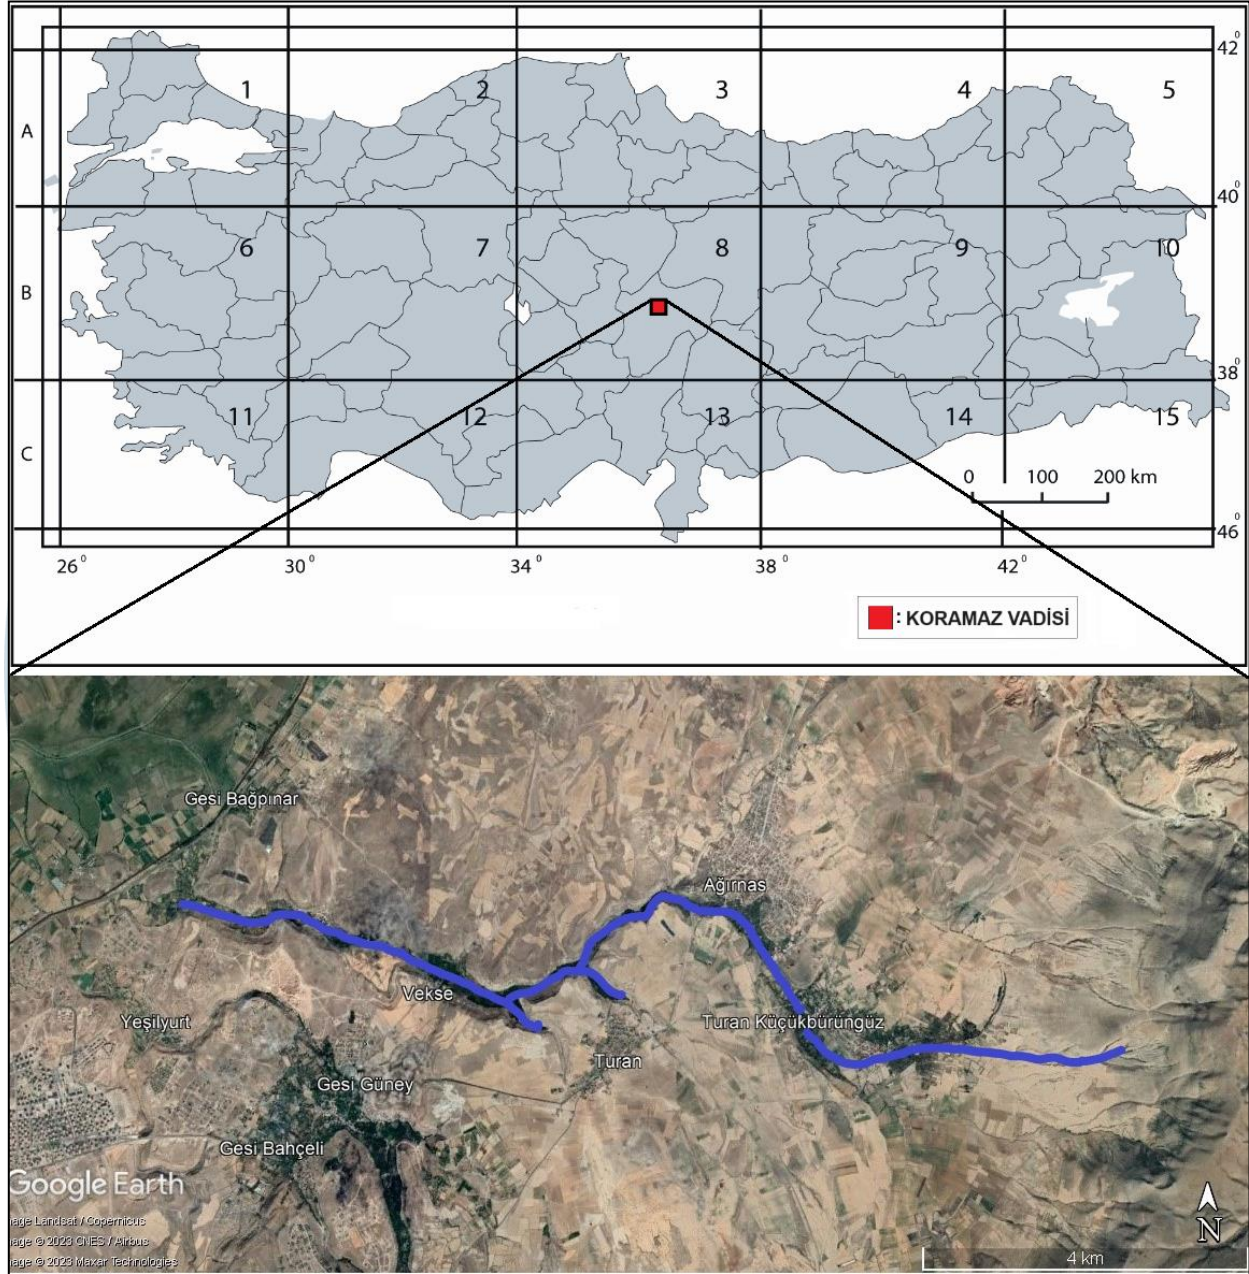

Akrokarp karayosunu familyası olan Pottiaceae yaklaşık 80 cins ve 1.400'den fazla tür ile briyofitler içerisinde yer alan en büyük familyalardan birisidir (Zander, 1993). Pottiaceae üyelerinin çoğunluğu kurakçıl karakterli habitatlara uyum sağlamış olsa da yarı kurak ve sucul habitatlarda yayılış gösteren taksonları da içermektedir (Inoue ve Tsubota, 2016).

Pottiaceae familyası içerisinde *Tortula* Hedw. kozmopolit bir cins olup üyeleri morfolojik açıdan oldukça çeşitlilik gösteren bir gruptur. Cins dünya çapında yaklaşık 100 tür içermektedir (Košnar ve Kolář, 2009). Bu türlerden biri olan *Tortula lingulata* Lindb. Avrupa'da nadir bulunmakta ve özellikle Estonya'da koruma altındadır. Avrupa IUCN Kırmızı Listesinde VU (hassas) kategorisinde değerlendirilen *T. lingulata* Asya'da sadece Tacikistan'dan rapor edilmiştir (Ingerpuu ve ark., 2008). Türkiye'de ise tür ilk kez Erciyes Dağı'ndan Türkiye için yeni kayıt olarak saptanmıştır (Kara ve ark., 2014). Bu çalışmada, Koramaz Vadisi'nden toplanan *T. lingulata* Türkiye'den ikinci kez kaydedilmiş olup Asya için üçüncü lokalite kaydı verilmiştir.

## MATERYAL VE METOT

### Çalışma Alanı

Koramaz Vadisi, İç Anadolu Bölgesi'nin Kayseri ili, Melikgazi ilçesi sınırları içinde yer almakta olan 16 kilometrelik bir deprem kırığı oluşumudur. Henderson (1961) tarafından Türkiye briyofitleri için oluşturulmuş kareleme sistemine göre B8 karesinde yer almakta olan vadi, Kayır Hanı mevkiinden başlamakta ve Korumaz Dağı'nda son bulmaktadır (Şekil 1).

Şekil 1. Henderson (1961) kareleme sistemi ve Koramaz Vadisi (Google Earth'den değiştirilerek)

Orta Anadolu'daki Ihlara Vadisi'nden sonra en uzun vadi olma özelliğini taşıyan Koramaz Vadisi'nin batı kısmında yükseklik 1165 metre iken, doğu ucunda 1500 metreye kadar çıkmaktadır. Yerleşim alanlarının da yer aldığı Koramaz Vadisi üzerinde Isbıdın (Bağpınar), Vekse, Dimitre (Turan), Ağırnas, Kiçi Bürgüz (Küçük Bürgüz), Üskübü (Subaşı) ve Ulu Bürgüz (Büyük Bürgüz) olmak üzere 7 adet köy bulunmaktadır. Vadinin en derin noktası Vekse ve Turan mahalleleri arasındaki Mançur mevkiidir (Cömert, 2008; Koramaz Vadisi, 2023; Yazlık, 2019; Allı, 2021).

Koramaz Vadisi UNESCO (Birleşmiş Milletler Eğitim, Bilim ve Kültür Örgütü) tarafından 2020 yılında Dünya Miras Listesi'ne dahil edilmesi üzere Dünya Miras Geçici Listesi'ne alınmıştır. Vadi sahip olduğu kültürel ve tarihi özelliklerinden dolayı uzun yıllardır kullanımda olduğu için bünyesinde tarihi taş evler, çeşmeler, su değirmenleri ve tümülüsler bulundurmaktadır (UNESCO, 2022). Ayrıca vadiye 6 adet yeraltı şehri de bulunmaktadır. Bunlardan en büyüğü 1273 metre uzunluğuyla Bürüngüz yeraltı şehri olup, Türkiye'de tespit edilen en uzun yeraltı şehridir (Allı, 2021; Koramaz Vadisi, 2023).

### Veri Kaynağı

Çalışmanın materyalini 19.11.2022 tarihinde Koramaz Vadisi'ne gerçekleştirilen arazi çalışmaları sırasında toplanan briyofit örnekleri oluşturmaktadır. Örnekler ilgili literatürler kullanılarak teşhis edilmiş olup Prof. Dr. Tülay Ezer'in kişisel koleksiyonunda ve Niğde Ömer Halisdemir Üniversitesi Herbaryumunda koruma altına alınmıştır (Zander, 1993; Cortini-Pedrotti 2001, Smith 2004; Košnar ve Kučera, 2010; Lüth, 2019; Dihoru, 2020).

### BULGULAR ve TARTIŞMA

*Tortula lingulata* Lindb. Revue Bryologique 7(3): 40–41. 1880. (Rev. Bryol.).

**Sinonimleri:** *Barbula montenegrina* Breidl. & Szyszył., *Tortula montenegrina* (Breidl. & Szyszył.) Broth.

**İncelenen örnek:** Türkiye, Orta Anadolu, Kayseri, Koramaz Vadisi, Ağırnas yeraltı şehri, giriş kapısı kumtaşı duvar üzeri (Şekil 2), 1301 m, 38°48'46"K 35°42'58"D, H.Ç.67, 19 Kasım 2022 (Niğde Ömer Halisdemir Üniversitesi Herbaryumu).

Şekil 2. *T. lingulata*'nın habitatı

### Türün Morfolojik ve Anatomik Özellikleri

*Tortula lingulata*, küçük yoğun yeşil demetler halinde görülmekte olup kısa çim (short turf) hayat formu göstermektedir. Bitki dik gövdelidir ve 2,5 mm uzunluğundadır. Dilsiz (lingulat) yapraklar kuruyken hafifçe kıvrık, nemliken neredeyse dik bir şekilde durur. Yaprak ucu yuvarlak ve kukullattır. Yapraklar 700 x 250 µm boyutlarında olup yaprak kenarı kıvrıktır. Yaprak taban hücreleri dar dikdörtgen (35 x 17 µm), düz ve renksizken yaprağın orta ve üst hücreleri (19 x 12 µm) yuvarlak ve güçlü papillalıdır. Yaprak kenar hücreleri yaprağın ortasından itibaren birkaç sıralı olarak farklılaşmış olup bu hücreler kalın çeperli, hafif papillalı veya papillasızdır. Ortalama 50 µm genişliğindeki kosta (orta damar) genellikle yaprağın ucunun hemen altında sonlanır (Şekil 3).

Şekil 3. *Tortula lingulata*. a. genel görünüm, b. kuru hali, c. nemli hali, d. yaprak, e. yaprak tabanı, f. yaprak ucu, g, h. yaprak enine kesitleri, i. yaprak kenarı enine kesiti

Seta parlak kırmızı, ince, bükülebilir ve yaklaşık olarak 3 cm uzunluğundadır. Kapsüller yumurta biçiminde, geniş ağızlı, peristom dişleri kuru olduğunda dik, sporlar ise 20-30 µm'dir (Smith, 2004). İncelenen örnek steril olup sporofit görülmemiştir.

### Türün Ekolojisi ve Dağılımı

Gölge habitatları tercih eden (sciöfit) *Tortula lingulata* Avrupa'da (Estonya, Litvanya, Rusya, Ukrayna, Gürcistan, Çekya, Almanya, Romanya) kumtaşı anakaya üzerinde yayılış gösteren nadir bir türdür (Dierßen, 2001). Karadağ ve Fransa'daki yayılış şüpheli olup *Tortula lingulata* var. *montenegrina* olarak rapor edilmiştir. *T. lingulata* Asya'da Tacikistan'dan ve Anadolu'dan kaydedilmiş olup dünyanın diğer kıtalarında rastlanılmamıştır (Ingerpuu ve ark., 2008; Kara ve ark., 2014; Dihoru, 2020). Bu çalışma ile Anadolu'dan ikinci kaydı ve Asya'dan da üçüncü lokalite kaydı verilmiştir. Avrupa Karayosunları, Ciğerotları ve Boynuzlu Ciğerotları Kırmızı Listesi'ne göre *Tortula lingulata* Avrupa ve AB (Avrupa Birliği) ülkeleri arasında VU (hassas) kategorisinde yer almaktadır (Hodgetts ve ark., 2019).

*T. lingulata* morfolojik olarak *T. obtusifolia* ile benzerdir. Ancak *T. lingulata*'nın yaprak ucunda sonlanan kostası ile geriye kıvrık yaprak kenarlarının birkaç sıra hücrelerinin kalın duvarlı ve hemen hemen papillasız olması *T. obtusifolia*'dan ayırdedici karakterleridir (Şekil 3, g-i) (Košnar ve Kolář, 2009).

### SONUÇ

*Tortula lingulata* Avrupa'da olduğu gibi Ülkemizde de nadir bir tür olup her iki kaydı da Orta Anadolu'da Kayseri ilinden verilmiştir. Türkiye'de briyofloristik çalışmalar hızla ilerlese de henüz çalışılmamış çok alan bulunmaktadır. Bu çalışma Türkiye'nin briyoflorasına katkı sağlayacaktır.

## TEŞEKKÜR

Bu çalışma, FMT 2022/12-LÜTEP nolu proje ile desteklenmiş olup Niğde Ömer Halisdemir Üniversitesi, Bilimsel Araştırma Projeleri Koordinasyon Birimine teşekkür ederiz.

#### Abstract

In this study, the inhibition effects of *Gladiolus halophilus* (GH) and *Gypsophila lepidioides* (GL) plants, which are endemic species growing in the chiselled soils of Erzincan province, Eastern Anatolia region, against tyrosinase and  $\alpha$ -glycosidase enzymes were investigated. Methanol extracts of leaves, branches and roots of the plants were used in the study. GHY, GHD and GHK coded extracts with IC<sub>50</sub> values of 75.17  $\mu$ g/mL, 105.02  $\mu$ g/mL and 83.92  $\mu$ g/mL showed good activity against tyrosinase enzyme under *in vitro* conditions. The tyrosinase  $\alpha$ -amylase inhibition effects of the extracts obtained from *G. lepidioides* were found to be lower. On the other hand,  $\alpha$ -amylase enzyme inhibition effects of *G. halophilus* plant extracts were found to be very low.

**Keywords:** *Gladiolus halophilus*, *Gypsophila lepidioides*, enzyme activity, tyrosinase,  $\alpha$ -glycosidase

#### INTRODUCTION

Many health problems have occurred in recent years with global warming, uncontrolled nutrition and increased genetic disturbances in the results affecting this. Diseases such as Alzheimer's diseases, skin cancer and diabetes are increasing very quickly (Yırtıcı, 2019). Treatment of these diseases with synthetic drugs is tesr in one place. Instead, studies on finding new therapeutic agents are increasing. It is hoped that the next decades, especially Alzheimer's disease and diabetes diseases, will affect approximately 81.1 million people by 2040 (Dhouafli et al., 2018). Diabetes's disease increases the risk of getting Alzheimer's disease. Therefore, studies on inhibition of  $\alpha$ -glucosidase, which is important in controlling hyperglycemia, are important (Li et al., 2018). In addition, Type II diabetes can cause hyperpigmentation on the skin, and inhibition of tyrosinase can prevent hyperpigmentation (Mendes et al., 2017).

Enzymes have important tasks in various physiological processes, such as growth in plants, development, metabolic events and responses to environmental stresses. The tyrosinase enzyme is a very important enzyme found in most living groups, including plants, bacteria and mammals. Hydroxylation of monophenols to o-diphenols using molecular oxygen as the mechanism of action; It is an enzyme containing copper that catalyzes the oxidation of o-quinones in o-diphenols. In the presence of molecular oxygen, they also play a role in the

conversion of monophenols to those dihydroxyphenols in addition to the oxidation reactions of o- and vic-OH group (3,4,5-trihydroxy) phenolic compounds (Vamos-Vigyazo et al., 1981). Tyrosinase and polyphenols are commonly found in plants. It is an enzyme that was first determined to be abundant in edible mushrooms and then in most fruits and vegetables, and whose importance is understood afterwards (Keleş et al., 1987). The most pioneering benefit of tyrosinases in plants can be expressed as the creature's resistance to microbial or viral infections and resistance to unfavorable climatic conditions. The amount of tyrosinase in plants depends on its variety, age, cultural processes and maturity (Spille et al., 1997).

Tyrosinase industry, pulp and paper industry, textile industry, pharmaceutical and environmental technology are well suited for some biotechnological applications. Apart from that, it can be used as an antioxidant and nutrient colorant (Slap meat al., 2007). The high content of secondary metabolites gives the plant very strong biological activity such as antioxidant, antimicrobial, insecticide, anticancer ( Demirtaş et al., 2017). Tyrosinase enzyme inhibitors are substances that can inhibit the activity of the tyrosinase enzyme. Tyrosinase is an important enzyme involved in the biosynthesis of melanin, the pigment responsible for the color of our skin, hair and eyes. While melanin is necessary to protect the skin from harmful UV radiation, its overproduction can lead to a variety of skin conditions such as hyperpigmentation, melasma and age spots. Tyrosinase inhibitors are activated here. Tyrosinase inhibitors can help fade these pigmented areas and improve the overall appearance of the skin. In addition, the fact that this basic problem cannot be solved and another missing problem in the body causes the emergence of other problems. The lack of these tyrosinase inhibitors can cause skin cancer (Yırtıcı et al., 2022).

Diabetes mellitus is a multifactorial global health disorder that is rising at an alarming rate. Alpha-glucosidase inhibitors are used to treat type 2 diabetes. Plants contain many compounds that inhibit this enzyme. Plant extracts can have a strong inhibitory effect on the enzyme due to both the main component and the synergistic effect. In addition, they have the important advantage of being able to interact directly with the enzyme found in the small intestine. Therefore, it has an important place in research (Dirir et al., 2022).

This study describes the inhibition of endemic *Gypsophila lepidioides* and methanol extracts from the *Gladiolus halophilus* plant grown in the chips of the Eastern Anatolia region against some enzymes. Since *Gypsophila lepidioides* and *Gladiolus halophilus* plants are not particularly on enzyme activity studies in the literature, the results that occur here are noteworthy in terms of being an important scientific data.

## MATERIALS AND METHOD

### Plant materials and Extracts preparation

In the June-July, plant materials used in the study were collected during the flowering period from the serpentine soils in the serpentine areas around Yücebelen Village and 3. km away from the direction of Yahşiler Village on the Kemah-İliç highway in Erzincan province. *Gypsophila lepidioides* (37S 484606 E, 4381349 N, 1320 m) was recorded under herbarium number Kandemir 11534B and *Gladiolus halophilus* (37S 492090 E, 4372902 N, 1461 m) was recorded under herbarium number Kandemir 11340 in Erzincan University herbarium. The dried plants were divided into three parts: leaf, stem and root. The aerial parts were ground into a fine powder using a laboratory mill. In methanol, 100 grams of powdered materials were macerated. The extract was subsequently concentrated under a vacuum in a rotary evaporator at 40 °C. All extracts were stored in dark and 4°C until working time.

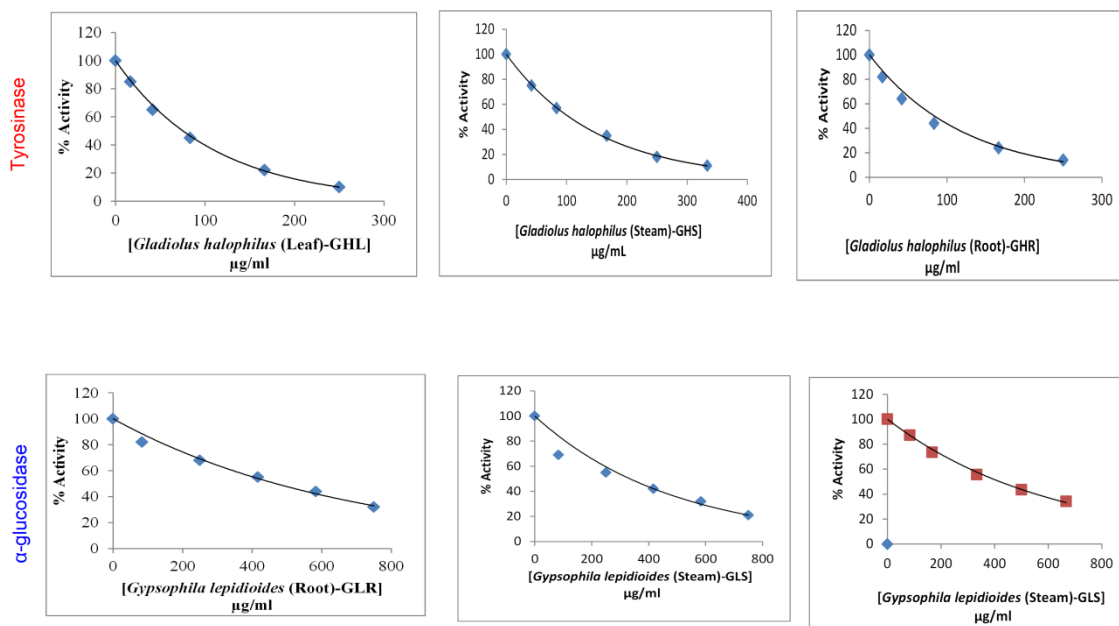

### Chemicals

All materials including chemicals and solvents used for enzyme activity studies and extraction procedures in this study were obtained from Sigma Aldrich, Fluka and Biological Industries (BI, USA).

### Enzyme activity tests

The tyrosinase inhibitory activity properties of extract were determined by making slight modifications in the dopachrome method used by Sarıkurkcu et al. (Sarıkurkcu et al. 2018, Tüfekçi et al., 2023). Accordingly, 25 mL of each extractant was taken from the stock extract solutions prepared at a ratio of 1:1 in DMSO and 40 mL of tyrosinase solution and 100 mL of sodium phosphate buffer (pH 6.8) were added and mixed. The mixture was incubated at 25°C for 15 minutes. After adding 40 mL L-DOPA, the mixture was incubated again at 25°C for 10 min. Absorbance was measured at 492 nm. Scutellarin compound was used as a positive control and the

result was determined by comparing the inhibitory effect of this compound on tyrosinase enzyme with the effect of the compound. For this, 1 mg of scutellarin compound was weighed and dissolved in 1 mL DMSO, then diluted ten times with distilled water. Enzyme activity was tested at five different scutellarin concentrations.

**Figure 1.** The inhibition effect of extracts on tyrosinase and a-glucosidase activity

The a-glucosidase inhibitory activity was determined using paranitrophenyl- a-D-glucopyranoside (pNPG) as substrate (Uysal et al., 2021). The extract (50 mL) was mixed with 50 mL a-glucosidase solution prepared in a buffer (sodium phosphate, pH 6.8), and 50 mL pNPG. The mix was incubated at 37°C for 15 min, and the reaction was followed with a spectrophotometer at 408 nm for 5 minutes.

The IC<sub>50</sub> value was calculated by plotting the percentage inhibition of enzyme activity against the sample concentration. The concentration at which the enzyme activity was inhibited by 50% was determined as the IC<sub>50</sub> value. The lower the IC<sub>50</sub> value, the stronger the inhibitory activity of the extract against a-glucosidase. To compare the inhibitory activity of the extract with acarbose, the IC<sub>50</sub> value of acarbose was also determined using the same method. The extract's inhibitory activity was then expressed in terms of mg standard equivalent per gram of extract, which represents the amount of extract required to achieve the same inhibitory activity as 1 gram of acarbose. This method allows for the quantification and comparison of the a-glucosidase inhibitory activity of the extract with a known standard (acarbose) and provides a measure of the extract's potential as an inhibitor of this enzyme.

## RESULTS AND DISCUSSION

**Table 1.** Enzyme inhibitory activities of *G. halophilus* and *G. lepidioides* methanol extract.

Plant	IC <sub>50</sub> =µg/mL	
	Tyrosinase	α-glucosidase
<i>Gladiolus halophilus</i> (Leaf)-GHL	75.17	420.08
<i>Gladiolus halophilus</i> (Steam)-GHS	105.02	-
<i>Gladiolus halophilus</i> (Root)-GHR	83.91	-
<i>Gypsophila lepidioides</i> (Leaf)-GLL	396.08	468.34
<i>Gypsophila lepidioides</i> (Steam)-GLS	344.85	334.85
<i>Gypsophila lepidioides</i> (Root)-GLR	465.19	266.59
Acarbose (Standart)	-	51.40
Scutellarin (Standart)	20.38	-

Tyrosinase and α-glucosidase inhibitory activity tests were performed to determine the anti-diabetic properties of methanol extracts from different branches of *G. halophilus* and *G. lepidioides* plants, as well as their protective properties for skin health. The results are presented as IC<sub>50</sub> values (**Table 1**).

Tyrosinase inhibitory activity also differs between plant species and the plant's own branches. Enzyme activity results on this plant species have been reported for the first time. It has been observed that the *Gladiolus halophilus* plant has a high inhibition effect against the tyrosinase enzyme. The IC<sub>50</sub> value of GHL extract was found as 75.17 µg/mL and was found to have the highest tyrosinase enzyme activity. GHR extract was determined to have the second highest inhibition with the IC<sub>50</sub> value of 83.91 µg/mL and an inhibition property that came later than the other two branches with the GHS extract 105.02 µg/mL IC<sub>50</sub> value.

The inhibitor effect of GL and GH extracts against the glucosidase enzyme has been found to be minimal. These differentials between the extras come from the adherence to the type and content of the chemical components it contains. The ability to inhibit this enzyme with its general reputation and any light exposed to the sun is generally seen in the aboveground parts. There is a mechanical synthesis event as a result of a kind of stress condition. The interesting thing is that this event fully supports the amount of content, and the extract belonging to the root part contains components that affect high inhibition (Figure 1).

## CONCLUSION

In this study, tyrosinase and α-glucosidase inhibitory effects of *G. halophilus* and *G. lepidioides* were tested. *G. halophilus* extracts have been an effective tyrosinase inhibitor in studied plants. In addition, the α-glucosidase enzyme inhibition of *G. halophilus* and *G. lepidioides* extracts was found low. Although *G. halophilus* extracts generally show a high activity, it is necessary to first identify the compounds responsible for the activity and conduct additional in vivo, in vitro studies in order to use it as an inhibitor.

## ACKNOWLEDGEMENTS

We thanks to Çankırı Karatekin University for their support in conducting this study.

#### Abstract

In this study, Quercimetrin (Quercetin 7-O-D-glucoside) compound has been isolated for the first time from *Centaurea paphlagonica*. The isolated compound was tested towards tyrosinase enzyme and examined by docking method using the molecular docking program. As a result of the enzyme inhibition experiment, scutellarin, which is the positive control, showed low inhibition against the tyrosinase enzyme, while quercimethrin exhibited higher inhibition. The IC<sub>50</sub> values of quercimetrin and scutellarin on tyrosinase inhibition effect were found to be 14.47 and 43.32 µM, respectively. In addition, molecular docking study was performed in order to explain the interactions of the quercimetrin with the target enzyme. The docking score for the quercimetrin was computed as to be -131.986. This study indicated that quercimetrin may be a good drug candidate in the development of tyrosinase inhibitors.

**Keywords:** Molecular docking, flavonoids, enzyme activity, tyrosinase, *Centaurea paphlagonica*

#### INTRODUCTION

Species of the genus *Centaurea* are generally distributed throughout Europe, Asia, North Africa and parts of America. This genus has a wide geographical distribution and the specific distribution of species may differ from species to species. These species are commonly found in alpine meadows, steppes, mountainous areas and agricultural land. On the other hand, the distribution of species within the genus *Centaurea* can vary depending on the specific species, and some species can only be found in certain geographical regions. The genus *Centaurea* is a plant genus with a fairly large number of species worldwide and in Turkey. The number of species of this genus worldwide is estimated to be around 700 to 800 (Kılıç et al., 2016). Due to the rich plant diversity of Turkey, the number of species of the genus *Centaurea* in Turkey is quite high. It is thought that there are more than 200 *Centaurea* species in Turkey (Tasar et al., 2018). These species are distributed in different geographical regions and habitats. Turkey's diverse climatic and topographic conditions increase the diversity of *Centaurea* species. The biological activities of plants belonging to the genus *Centaurea* may vary depending on the plant species and the components they contain. Since *Centaurea* species contain unique compounds, they offer a wide range of activity potential of the plant species. The high content of secondary metabolites gives the plant very strong biological activity such as antioxidant, antimicrobial, insecticide, anticancer (Demirtaş et al., 2017).

Enzymes play important roles in various physiological processes in plants, such as growth, development, metabolism and responses to environmental stresses. *Centaurea* species produce antioxidant enzymes such as superoxide dismutase (SOD), catalase and peroxidase. These enzymes help the plant fight oxidative stress by neutralising harmful reactive oxygen species (ROS) produced during various metabolic processes and in response to environmental stresses. Some *Centaurea* species increase the synthesis of phenolic compounds by activating enzymes such as phenylalanine ammonia lyase (PAL) and polyphenol oxidase (PPO) in defence against herbivores and pathogens. *Centaurea* species possess a number of metabolic enzymes involved in processes such as photosynthesis, respiration and synthesis of secondary metabolites such as alkaloids and flavonoids. These enzymes play key roles in plant growth and response to environmental cues. In response to various environmental stresses such as drought, salinity and pathogen attack, *Centaurea* species can modulate

the activity of stress-associated enzymes such as abscisic acid (ABA)-related enzymes and defence enzymes such as chitinases and glucanases. Some *Centaurea* species are used in traditional medicine and their enzyme activities may be related to their therapeutic properties. For example, some species may contain enzymes involved in the production of bioactive compounds with potential medicinal properties.

Research on *Centaurea* species shows that some species have tyrosinase enzyme activity. Tyrosinase is an enzyme responsible for the synthesis of phenolic compounds and plays a critical role in melanin production. Melanin is a pigment that provides pigmentation in the skin, hair and retina of the eye. Tyrosinase activity may be involved in various biological functions in plants, such as pigment synthesis, defence responses and antioxidant protection (Yırtıcı et al., 2022). Some *Centaurea* species may possess tyrosinase activity, and this activity may help the plant to regulate its phenolic components and melanin production. In particular, it is thought that some *Centaurea* species may have the potential to provide pigmentation regulation or antioxidant properties in medicinal or cosmetic uses.

Skin cancer, one of the most prevalent cancers in the world, continues to increase at alarming rates in both incidence and fatality (Ismaya et al., 2011). One of the most dangerous effects of skin cancer is melanoma, which is marked by active melanocyte proliferation and increased melanin pigment accumulation, resulting in skin pigmentation and discolouration. Tyrosinase enzyme levels that have been upregulated seem to have a key role in the increased production and storage of melanin in melanocytes (Rao et al., 2013). Tyrosinase is a multifunctional and copper-containing enzyme and has very important functions in plants and animals. This enzyme is known to form dopaquinone via oxidation from L-3,4-dihydroxyphenylalanine (L-dopa) and then undergoes a series of reactions to form melanin (Sasaki et al., 2002). The suppression of melanin synthesis can be achieved by inhibiting tyrosinase activity.

In this study, quercimetrin compound was isolated from the *Centaurea paphlagonica* and its inhibition effect against the tyrosinase enzyme was studied *in silico*.

## MATERIALS AND METHOD

### General

Molecular docking calculations were made using the Molegro Virtual Docker program. Interactions between quercimetrin and tyrosinase enzyme were visualized with the BIOVIA Discovery Studio program. The 3-D structure of the tyrosinase enzyme (PDB ID: 2Y9X)<sup>4</sup> was taken from the RCSB database ([www.pdb.org](http://www.pdb.org)). The 3D chemical structure of the isolated compound was taken as sdf format from the BIOVIA Discovery Studio program. The active site of the tyrosinase enzyme was determined and the docking procedure was applied to analyze the interactions of the quercimetrin ligand in this active site. The coordinates of position of quercimetrin are X: -9.94907 Y: -28.2774 and Z: -44.4249 at 46.08 Å<sup>3</sup> volume, 166.4 Å<sup>2</sup> surface.

### Pure compound

Quercimetrin (Quercetin 7-O-D-glucoside), a flavonoid glycoside, was isolated from *Centaurea paphlagonica* for the first time. The structure of the compound has been elucidated using NMR, HRMS-MS and a series of spectroscopic methods.

### Enzyme activity tests

The tyrosinase inhibitory activity properties of quercimetrin compound were determined by making slight modifications in the dopachrome method used by Sarıkurkcu et al. (Sarıkurkcu et al. 2018, Tüfekçi et al., 2023).

Accordingly, 25 µL of each extractant was taken from the stock extract solutions prepared at a ratio of 1:1 in DMSO and 40 µL of tyrosinase solution and 100 µL of sodium phosphate buffer (pH 6.8) were added and mixed. The mixture was incubated at 25°C for 15 minutes. After adding 40 µL L-DOPA, the mixture was incubated again at 25°C for 10 min. Absorbance was measured at 492 nm. Scutellarin compound was used as a positive control and the result was determined by comparing the inhibitory effect of this compound on tyrosinase enzyme with the effect of the compound. For this, 1 mg of scutellarin compound was weighed and dissolved in 1 mL DMSO, then diluted ten times with distilled water. Enzyme activity was tested at five different scutellarin concentrations.

## RESULTS AND DISCUSSION

In this study, the inhibition effect of quercimetrin on tyrosinase enzyme were investigated. According to the result obtained from activity-concentration graph (Figure 1), it was determined that the compound inhibited the tyrosinase enzyme. The  $IC_{50}$  values of quercimetrin and scutellarin are 14.47 and 43.32  $\mu\text{M}$ , respectively. According to  $IC_{50}$  values, quercimetrin are compound with the highest inhibitory effect.

Figure 1. Activity %–Concentration graph of compound.

Molecular docking tests were conducted to identify the types of binding interactions and the amino acid residues relevant for the produced compound's biological activity. In this study, docking simulation was used to investigate the binding pocket of the tyrosinase protein receptors, and the outcomes were examined to identify the affinity scores and mode of contact (hydrophilic and hydrophobic contacts). 2D and 3D binding mode of quercimetrin in the binding pockets of the tyrosinase receptor is shown in Figure 2. Quercimetrin makes conventional hydrogen bonds with Glu322, Ala323, Cys83 and Met280 of tyrosinase. Also, it makes pi-donor hydrogen bond with Asn 81 of respective receptor. The residues Glu322 and His263 interact with quercimetrin by electrostatic interactions. In addition, quercimetrin makes pi-pi stacked interaction with His85 and pi-alkyl interaction with Val283 in the active site of the enzyme. The possible interaction types and energies obtained Molegro Virtual Docker (MVD) programme are given in Table 1. According to the results of docking calculation, the steric and hydrogen bond interactions played a major role in the binding of the said compound to the active site of the enzyme in protein–ligand interactions.

Figure 2. The docking conformation of quercimetrin-tyrosinase complex with lowest energy. (a) 3D view of the best selected conformation. (b) 2D view of the binding site interactions.

**Table 1.** MolDock score, electrostatic, steric interaction and the hydrogen bond energy of the docked quercimetrin.

Energy overview: Descriptors	Quercimetrin
Protein–ligand interactions	-167.814
Internal ligand interactions	33.617
Protein ligand hydrogen bonds	-15.15
MolDock Score	-131.986

## CONCLUSION

Tyrosinase inhibitors uses as medicine in the prevention of Alzheimer, Parkinson and skin cancer diseases. The isolated compound is a biologically effective compound with therapeutic potential. This compound effectually obstruct the activity of tyrosinase with IC<sub>50</sub> values in the micromolar range. The current in silico study indicated that the quercimetrin may be a good agent in the development of selective tyrosinase inhibitor to prevent complications of this diseases in people with Alzheimer, Parkinson and skin cancer diseases.

#### Abstract

SARS-CoV-2 is the causative agent of the COVID-19 pandemic, causing a global health emergency, and affecting millions of people around the world. The objective of this work is to realize an epidemiological study about the evolution of COVID-19 in the five countries of North Africa (Morocco, Algeria, Tunisia, Libya, and Egypt) between January 2020 and May 2023. Methods applied were the observation and analysis of an international database using SPSS and Excel to compare the number of cases, number of deaths as well as the rate of vaccinations between the countries of this geographical area. Results obtained showed a total of 3,717,862 new cases and 83,757 deaths were recorded over the three years in these North African countries, where 2021 represented the most tragic year with the most COVID-19 cases and the most deaths (1767,410 and 50,341, respectively), and that the most affected countries were Morocco with 1,272,490 cases (34%) and Tunisia with 150,962 cases (31%). Similarly, the highest number of deaths was recorded in Tunisia with 29,331 deaths (35%), and in Egypt with 24,812 (30%). In addition, Morocco (47%) marked the highest rate of vaccinations out of a total of 384 851 69 injections. The COVID-19 pandemic has been considered a global health problem affecting each country in different ways depending on their people, control strategies, and vaccination campaigns.

## POSTER PRESENTATION

### Impact of empirical antibiotic therapy on the management of native valve infective endocarditis with negative blood cultures : analysis of 45 cases

Harbi\_Wafa<sup>1\*</sup>, Manamani\_Leila<sup>2</sup>

<sup>\*1</sup>University Badji Mokhtar, Faculty of Medicine, ANNABA, ALGERIA.

#### Abstract

Infectious endocarditis is a complex and heterogeneous pathology with significant morbidity and mortality. its management is essentially based on the eradication of microorganisms by bactericidal antibiotic therapy. We conducted a retrospective analysis of 45 patients hospitalized for infective endocarditis of native valve with negative blood culture from January 2021 to June 2023, the average age was 35 years with a male predominance. 60% of blood cultures were negative because of untimely prehospital antibiotic prescription.

Most of the patients had vegetation visible on transthoracic echocardiography, a minority had a mitro-aortic trigone abscess diagnosed on transesophageal echocardiography. All our patients were treated with a dual therapy combining vancomycin and gentamycin for two weeks followed by vancomycin monotherapy for 4 weeks, a favorable clinical and biological response was observed in 30 patients, no improvement with persistence of fever was observed in 10 patients, 5 patients underwent urgent cardiac surgery.

However, the main side effects observed with this dual therapy were renal failure (15) and allergic reactions such as urticaria (6) and Lyell syndrom (2)

This suggests that the use of a probabilistic antibiotic therapy combining vancomycin and gentamycin has been shown to be effective in the management of culture-negative infective endocarditis, due to its broad-spectrum, strong synergy and potentiation of bacterial activity, nevertheless, its tolerance and the side effects of each molecule still pose problems, including renal toxicity, often leading to premature discontinuation of gentamicin.

<sup>\*1</sup> University of Belhadj Bouchaib, Faculty of Science and Technology, Chemistry department, Ain Temouchent, Algeria.

<sup>4</sup> University of Tlemcen, Faculty of Science and Technology, Chemistry department, Tlemcen, Algeria.

#### Abstract

Almost all organic compounds that contain heterocyclic nitrogen are biologically active and have been used in the synthesis of several pharmaceutical molecules. Propargylamines are the most molecules which used to synthesis drugs molecules as rasagiline and selegiline for the Parkinson traitement. The C-C coupling reaction is a simple way to afford new structure of propargylamines in the presence of catalysts.

To ensure the synthesis of propargylamine with good yields, we used metal catalysts of binary copper iron phosphate catalyst to activate the reaction. The catalyst was characterized by several methods as XRD, MET and UV-Vis. Also, the catalyst presented a high activity and good stability for five runs.

<sup>1</sup>University of Belhadj Bouchaibof Ain Temouchent, Algeria.

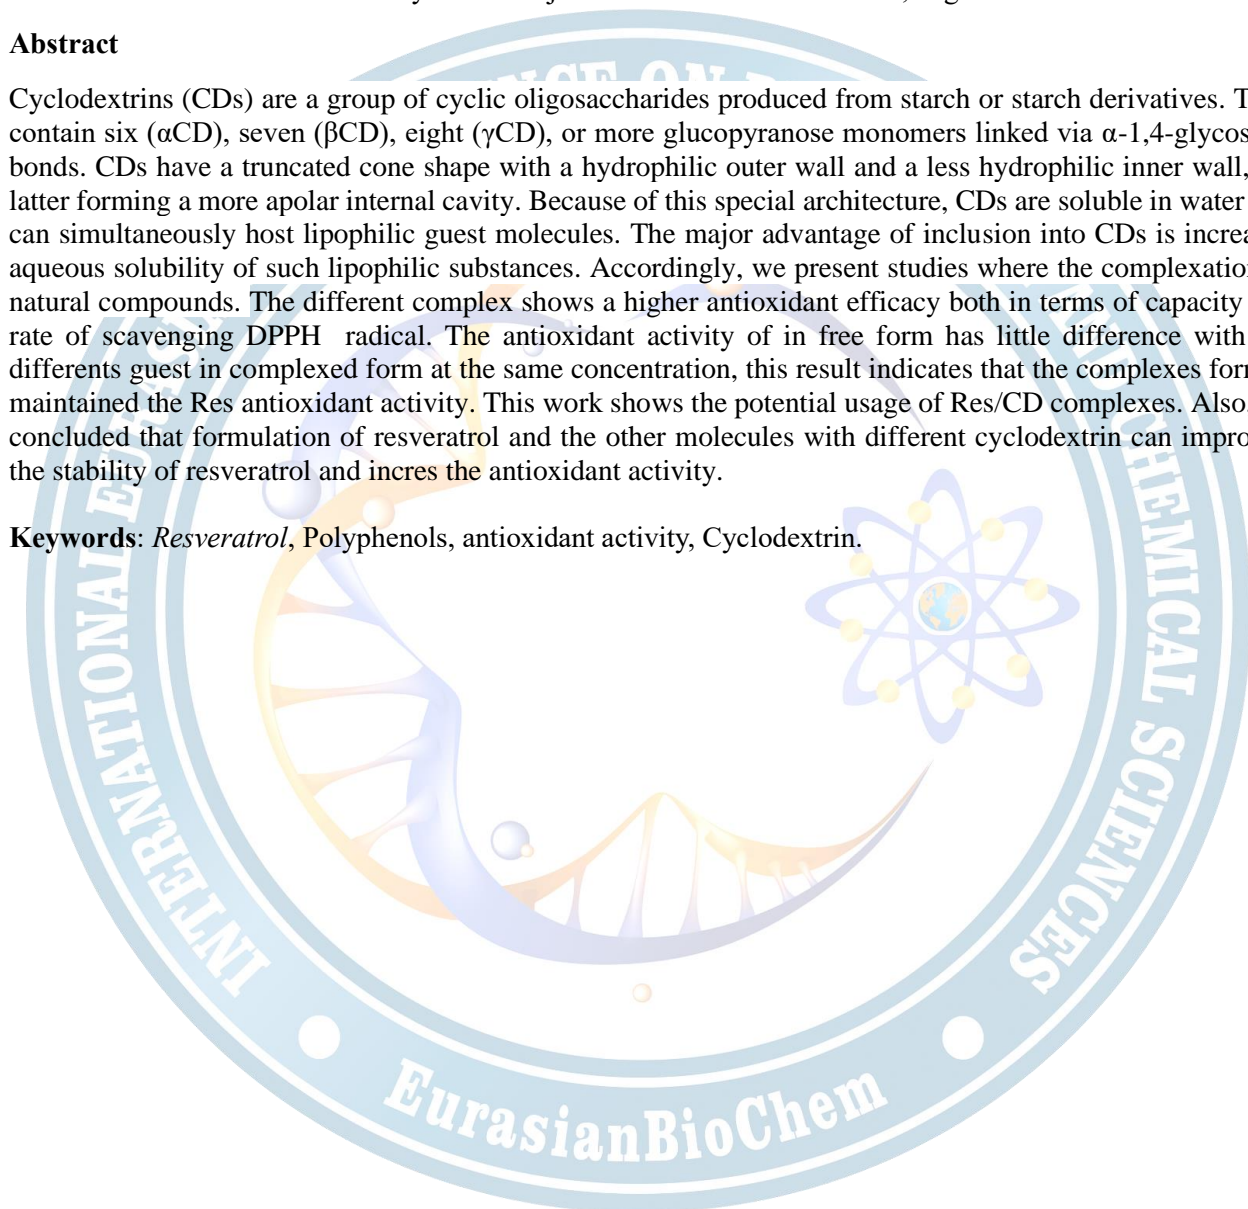

<sup>2</sup>University Abou Bekr Belkaid of Tlemcen, Algeria.

<sup>3</sup>University of Belhadj Bouchaibof Ain Temouchent, Algeria.

#### Abstract

Cyclodextrins (CDs) are a group of cyclic oligosaccharides produced from starch or starch derivatives. They contain six ( $\alpha$ CD), seven ( $\beta$ CD), eight ( $\gamma$ CD), or more glucopyranose monomers linked via  $\alpha$ -1,4-glycosidic bonds. CDs have a truncated cone shape with a hydrophilic outer wall and a less hydrophilic inner wall, the latter forming a more apolar internal cavity. Because of this special architecture, CDs are soluble in water and can simultaneously host lipophilic guest molecules. The major advantage of inclusion into CDs is increased aqueous solubility of such lipophilic substances. Accordingly, we present studies where the complexation of natural compounds. The different complex shows a higher antioxidant efficacy both in terms of capacity and rate of scavenging DPPH radical. The antioxidant activity of in free form has little difference with the different guest in complexed form at the same concentration, this result indicates that the complexes formed maintained the Res antioxidant activity. This work shows the potential usage of Res/CD complexes. Also, we concluded that formulation of resveratrol and the other molecules with different cyclodextrin can improve the stability of resveratrol and increase the antioxidant activity.

**Keywords:** *Resveratrol*, Polyphenols, antioxidant activity, Cyclodextrin.

### Valorization of urban wastewater treatment sludge in the construction field

Cheurfi Wassila<sup>\*1</sup>, Kebabi brahim<sup>2</sup>

<sup>1,2</sup>Constantine Mentouri University, Department of Chemistry, Faculty of Sciences, Pollution and Water Treatment Laboratory, Route Ain El Bey, Constantine 25000, Algeria

#### Abstract

The objective of this work is to identify alternatives that allow better management of urban wastewater treatment sludge. For this reason, a characterization of the annual sludge collected from the wastewater treatment plant in the city of Jijel Algeria is necessary. Physical, chemical and spectroscopic analyzes relating to the characterization of sludge. Based on a set of diverse and complementary techniques, such as XRF, DRX, FTIR, TG DSC. Thus the measurement of some physico-chemical parameters such as: density, porosity, pH, electrical conductivity, volatile matter, loss on ignition. This characterization aims to describe the composition of the sludge and ash of the sludge studied and distinguish the optimal conditions for obtaining residues with appropriate characteristics for better valorization.

The qualitative and quantitative analysis by different XRF, DRX, IR, TG-DSC techniques of the sludge collected during the years 2021-2022-2023 reveals that the main composition of the Jijel mud is stable and presents no danger during their reuse. The phases obtained by calcination of sludge ( $\text{SiO}_2$ ,  $\text{CaO}$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ ) are very essential in the field of manufacturing construction materials, which are the main minerals of clinker. Substituting calcined sludge in cement mortar does not present any risk to the resistance of the material but, on the contrary, allows it to be improved.

**Keywords:** sludge, wastewater, construction, clinker

<sup>4</sup>Mathematical and Subatomic Physics Laboratory, Exact Sciences Faculty, Physics Department, Constantine 1 University, Algeria

#### Abstract

The *Robusta* spent coffee grounds (SCG) were used as the basic material to produce activated carbon with potassium hydroxide (KOH). Initially, the SCG was washed with deionised water and dried at 70°C for 24h. After *pyrolysis* process at 700°C for 1h, the obtained SCG was mixed and stirred with KOH (1:1) at 80°C for 1h and subjected to calcination *under the same conditions*. The resulting material was mixed with H<sub>2</sub>SO<sub>4</sub> (1N) and stirred at 90°C for 1h. After filtration and dryness, the chemical functional groups of SCG activated with KOH were checked using Fourier transform infrared spectroscopy analysis (FTIR) in the range of 4000-400 cm<sup>-1</sup>. The spectrum exhibits a peak at 3650 cm<sup>-1</sup> related to O-H stretching vibration. Also, a peak at 2987-2900 cm<sup>-1</sup> indicated C-H stretching modes. The peaks found at about 1394 and 1066 cm<sup>-1</sup> are assigned to the stretching vibration of the C-O bond. *Preliminary results of the antioxidant assay show that the SCG had a weak DPPH radical scavenging ability compared to standard. The SCG may serve as a new basic material with antioxidant potential and the enhancement of such effect needs the amelioration of the synthesis process.*

**Keywords:** SCG, KOH, Carbonization, FTIR, Antioxidant activity

## POSTER PRESENTATION

### Epidemiology and resistance to antibiotics of Enterobacteriaceae isolated from urinary tract infections in hospital

KHELILI Kaoutar\* (ORCID: <https://orcid.org/0009-0001-5571-257X>)

\*Frères Mentouri Constantine 1 University, Natural and Life Sciences Faculty, Applied Biology Department, Constantine City, Algeria Country.

#### Abstract

*Enterobacteriaceae* are the agents most frequently implicated in urinary tract infections. Their antibiotic resistance justifies epidemiological surveillance. The objective of our work is to carry out a statistical and epidemiological retrospective study over three years in order to calculate incidence and assess risk factors related to urinary *enterobacteriaceae* infections in hospitalized patients. Our results show that urinary infection is more common in women than in men. *Escherichia coli* dominates the epidemiological profile followed by *Klebsiella sp.* The study of the resistance profile of *enterobacteriaceae* has shown that most of them have a high resistance to penicillins, cephalosporins of first generation and trimethoprim. The epidemiological cohort investigation reveals that the female sex and the misuse of penicillins present a risk factor for urinary tract infection caused by *Escherichia coli*. The results of this study show a worrying increase in antibiotic resistance in uropathogenic *Enterobacteriaceae*. This requires rational prescription of antibiotics.

**Keywords:** urinary tract infections, *Enterobacteria*, antibiotic resistance, epidemiology, risk factors.

#### Abstract

Forty one cases of sudden found dead free-range poultry were examined for the presence of *Aspergillus spp.* and avian *Escherichia coli*. The samples were collected from 10 different poultry flocks that had continuously been treated for respiratory clinical manifestations, low growth rates and poultry weakness. The post-mortem findings of the tested broiler chicks were mainly focused on air sacs, pericardium and liver. This case study was conducted in Elbasan district, during early spring months (March-April 2023).

Clinical and postmortem investigations; bacteriological and mycological examinations were carried out for each sample at the Veterinary Public Safety Laboratory, nearby the Faculty of Veterinary Medicine, Tirana. Simultaneous incidence of avian aspergillosis and colibacillosis resulted positive for 14 cases of the tested poultry (34, 14%), meanwhile 12 cases resulted positive only for *E.coli* (29, 26%). In the present study, the positive *E.coli* strains (n = 26) were evaluated against 6 different antimicrobial drug classes with the following resistance rates: Quinolones (46, 15%), Amphenicols (61, 53%), Tetracyclines (84, 61%), Penicillines-like (92, 3%), Sulfonamides (69, 23%), Aminoglicosides (73, 07%), by disk diffusion method. High levels of antibiotic-resistance were encountered in all of the 26 *E. coli* strains, where 14 *E. coli* strains (53, 84%) were identified as multi-resistant.

Previous national studies have been conducted for the presence of antibiotic-resistant avian *Escherichia coli* in poultry, but no data is yet reported on the correlation of colibacillosis infection incidence with respiratory mycosis. Continuous treatment of the poultry flock contributes to the development of antibiotic-resistant bacteria and in lack of poultry immunity towards other infectious agents. The preliminary results highlight that the incidence of multi antibiotic-resistant *E.coli* may be associated with other poultry respiratory diseases that should require further field investigations.

**Keywords:** *Escherichia coli*, *Aspergillus spp.*, poultry, Antibiotic-resistance, Albania.

#### Abstract

The purpose of this study was to evaluate the protective effect of 4 plant ethanolic extracts with antioxidant properties: gum rockrose (*Cistus ladanifer*), false yellowhead (*Inula viscosa*), french lavender (*Lavandula stoechas*), and oleander (*Nerium oleander*). After evaluating the biological disturbances at low doses of ionizing radiation on *Tetrahymena pyriformis*, the protective effect of the 4 plant ethanolic extracts was evaluated by comparative studies of the effects on growth (generation time and number), on morphology and on physiology of the cell model by analyzing some metabolic enzymes and antioxidant biomarkers. The results obtained after exposure to ionizing radiation allowed us to highlight certain aspects of disturbances on the growth, morphology and physiology of the cell model, and to characterize the protective properties of the studied plant extracts. Some extracts are characterized by their important protective activities, which can be correlated to their antioxidant properties. These activities allowed the protozoan to escape the disruptive effects of ionizing radiation with a resumption of growth and a normal morphological form. The physiological parameters studied (GAPDH, SDH, Catalase, SOD, Peroxidases ...) were also improved. These encouraging results shed light on the radioprotective effect of plant extracts, one of the most little-studied virtues.

**Keywords:** Protective properties, Plant extracts, Ionizing radiation, *Tetrahymena pyriformis*.

## POSTER PRESENTATION

### Development of rapid chemiluminescent enzyme immunoassay for determination of nonylphenol in drinking water

Anna N. Berlina\* (ORCID: <https://orcid.org/0000-0002-3761-7472>), Maria Y. Ragozina, Nadezhda S. Komova (<https://orcid.org/0000-0002-3229-9073>), Kseniya V. Serebrennikova (ORCID: <https://orcid.org/0000-0001-9507-4085>), Anatoly V. Zherdev (ORCID: <https://orcid.org/0000-0003-3008-2839>), Boris B. #### Abstract

Nonylphenol is a more toxic decomposition product than the corresponding ethoxylate, which is used by humans in everyday life as part of various detergents. Having its effect on the reproductive, immune and nervous systems, this substance leads to disruption of the functioning of organ systems. Studies of toxic effects have led to the rationing of nonylphenol in drinking water. It is listed as priority pollutant in EPA's Contaminant Candidate List (US EPA, 2022). The main tools for determining nonylphenol are chromatographic methods. However, they cannot be used for screening purposes. In this regard, the development of relatively fast methods that allow the specific determination of the target analyte immediately in a series of water samples is an urgent task. The goal of this work was to develop a rapid chemiluminescent enzyme-linked immunoassay (ELISA) for nonylphenol. For this purpose, hapten-protein conjugates were synthesized and rabbit antibodies were obtained. The principle of the analysis is based on the competitive interaction between an immobilized analyte (hapten-protein conjugate) and a free one (nonylphenol) in the sample for the binding site of specific antibodies in the wells of a microplate. Goat anti-rabbit IgG antibodies labeled with horseradish peroxidase (HRP) were used as a developing immunoreagent. The HRP substrate of choice was luminol, combined with the enhancer p-iodophenol. By optimizing the composition and quantity of immunoreagents, the duration of the competitive stage, the detection time, it was possible to reduce the detection limit of nonylphenol to 7 ng/ml. The working range was 19-600 ng/ml. The achieved parameters are significantly better compared to the traditional approach with the use of colorimetric peroxidase substrate. Using colorimetric detection, the detection limit for nonylphenol was 55 ng/mL with the working range of 190-1300 ng/ml. The developed analysis was successfully applied to drinking water samples.

This work was supported by the Russian Science Foundation (grant no. 22-13-00293).

<sup>2</sup>Hellenic Pasteur Institute, Laboratory of Medical Microbiology, Athens, Greece

#### Abstract

Snakebites are a significant public health concern in many parts of the world, including Europe. Medically important cases of snakebite in the Old Continent are caused mainly by snakes belonging to the Viper family (*V. berus*, *V. aspis*, and *V. ammodytes*). It is well known that snake venom is a complex mixture, and not all the components contribute to its toxicity<sup>1</sup>. Snake venom phospholipases A<sub>2</sub> (svPLA<sub>2</sub>), which are found in almost all venomous snake families, play a central role in snakebite toxicity and, particularly in *Vipera* species, possess the highest percentage among the venom components. Consequently, svPLA<sub>2</sub> may represent a promising candidate for achieving wide-spectrum antivenom activity<sup>2</sup>. Furthermore, currently available snake antivenoms produced in horses, immunized with whole venoms frequently cause adverse reactions in the patients administered<sup>3</sup>. On the contrary, IgY antibodies, which are analogous to mammalian IgGs, can be extracted from the egg yolk in large quantities with high yields, and do not activate the human complement system<sup>4</sup>. Thus, IgY technology has the potential to offer a sustainable, economical, and ethical alternative to traditional antivenom production methods. In this research, two peptide epitopes (10mers) from the C-terminal segment of PLA<sub>2</sub>s of *V. berus* and *V. ammodytes* snake species were synthesized and conjugated via thioether bond to the CH<sub>3</sub>CO-[K-Aib-C(1,3-CH<sub>2</sub>CONH<sub>2</sub>)<sub>4</sub>-NH<sub>2</sub> [CPSOC(3,9Acm)] peptide carrier. Hens were vaccinated with the immunogenic conjugates, and the specific IgY antibodies were isolated from the egg yolk. ELISA was employed to investigate the produced antibodies' potency to recognize both homologous and heterologous Viper venoms. Data shows that the produced antibodies have the ability to capture various Viper venoms from Greek territory.

**Keywords:** IgY antibodies, antivenom, CPSOC(3,9Acm), PLA<sub>2</sub>, *V. berus*, *V. Ammodytes*.

#### Acknowledgements

The research work was supported by the Hellenic Foundation for Research and Innovation (HFRI) under the 3<sup>rd</sup> Call for HFRI PhD Fellowships (Fellowship Number:5428).

Also, we are grateful to Ilias Strachinis and Thomas Daftsios for their valuable contribution to this research by providing us with the appropriate viper venoms.

<sup>2</sup> University Abou Bakr Belkaid, Faculty of sciences, Department of chemistry, Tlemcen, Algeria.

#### Abstract

Although pharmaceutical products play a major role in our lives and well-being, their contamination of our environment becomes a real public health problem. Among several known purification techniques, biosorption is one of the most economical and environmentally friendly method. This led us, among other things, to choose to use a residue from the food industry as biosorbent.

In our study, we are interested in eliminating by biosorption paracetamol from an aqueous solution by orange peel. For this, we studied the effect of some operating parameters on the adsorption efficiency (contact time, solution pH, temperature). Then we interested in studying some kinetic models and thermodynamic parameters to try to understand the mechanism that governed the biosorption process. The results showed that the kinetics were fast and well-adjusted with the pseudo-second order, and the maximum adsorption capacity was 9.94 mg/g. After the thermodynamic study, it was found that the process was favourable, spontaneous ( $\Delta G_0 < 0$ ) and endothermic ( $\Delta H > 0$ ) and physico-chemical nature. The results obtained using this new green material as a biosorbent obtained from *Citrus sinensis* plant has proven to be an effective, economical and environmentally friendly alternative for the purification of water contaminated with paracetamol.

Laboratoire des Sciences et Tehniques de l'eau et environnement

#### Abstract

An isocratic RP-HPLC method has been validated for the dosage of Neurovit in pharmaceutical tablet form containing a binary mixture of Pyridoxin and Thiamin. The Chromatographic separation was performed on C 18 analytical column (4,6 mmx 250 mm, 5  $\mu$ m particle size), using UV detection at 280 nm. With a mobile phase containing water with triethylamine 2 % and sulfuric acid ( pH = 2,5) at a flow rate of 1mL/min. The results of the study demonstrate that the method is specific, accurate, precise and reproducible, it could be applied for the quantitative analysis of thiamine and pyridoxin in Neurovit tablets.

#### Abstract

The three-component coupling of an amine, an alkyne and an aldehyde (A3) is a C-C coupling reaction that yields propargylamines, intermediates widely used in the preparation of biologically active and therapeutically useful products. These reactions involve the use of homogeneous and heterogeneous metal-based catalysts to activate the C-H bond and form a new C-C bond. In this work, we synthesize propargylamine in "one-pot" via A3 coupling reaction of an aldehyde, an alkyne and an amine in the presence of a heterogeneous iron-based catalyst in nanoparticles form. This material is prepared by hydrothermal method and characterized by different methods. The iron-catalysts present a good activity in the synthesis of propargylamine which good yield.

**Keywords:** A3 coupling, Heterogeneous catalyst, Hydrothermal method, Nanoparticles, Propoargylamine synthesis.

## POSTER PRESENTATION

### Root-Associated Endophytes in Five Co-Occurring Orchid Species: Isolation and Molecular Identification

Ines Harzli<sup>1\*</sup> (ORCID: <https://orcid.org/0000-0003-4009-2993>) and Yasemin Özdener Kömpe<sup>1</sup> (ORCID: <https://orcid.org/0000-0003-1649-4298>)

<sup>1</sup>University of Ondokuz Mayıs, Faculty of Science, Department of Biology, Samsun, Turkey.

#### Abstract

The diversity of internal symbiotic fungi known as endophytes, which are associated with orchids, is vast. While previous research on orchid endophytic fungi primarily concentrated on endophytes linked to plant roots, there has been a growing inclination to investigate non-mycorrhizal endophytes from orchids due to their significant physiological functions and their potential as reservoirs of novel bioactive compounds. In this present study, we have successfully identified both morphologically and molecularly the fungal endophytes isolated from the roots of five terrestrial orchid species found in the same habitat: *Anacamptis papilionaceae*, *Orchis provincialis*, *Neotinea tridentata*, *Serapias orientalis*, and *Spiranthes spiralis* in the Samsun province (Turkey). To isolate and identify endophytic fungi associated with orchid species, root samples were collected during April 2022. The isolates underwent characterization through both morphological and molecular techniques. Molecular identification revealed that only 1 fungal strain was identified at family level, including Herpotrichiellaceae (isolated from *O.provincialis*). 2 fungal strains were identified at genus level, including *Trichoderma* (shared by *S.spiralis* and *O.provincialis*) and *Tomentella* (shared by *O.provincialis*, *A.papilionaceae*, and *S.orientalis*). 4 fungal strains were identified at species level, including *Rhizopus arrhizus* (shared by *S.spiralis*, and *N.tridentata*), *Ilyonectria robusta* (shared by *A.papilionaceae* and *N.tridentata*), *Fusarium oxysporum* (Shared by *S.spiralis*, *O.rovincialis*, and *N.tridentata*), and *Penicillium expansum* (*O.provincialis*, *S.orientalis*, and *A.papilionaceae*). In this research, we were able to identify culturable endophytic fungi of different orchid species found in the same habitat. These results may indicate that endophytic fungal partner(s) of orchids may vary and this could allow us to investigate their importance in the preservation and growth of orchids, as well as their possible use in uncovering bioactive compounds.

**Keywords:** Endophytes, Fungal diversity, Orchidaceae

#### Abstract

Food is one of the basic needs for sustaining life. As the population grows, hunger is a growing concern around the world. All foods, especially protein foods, are essential for global nutrition. However, rising food demands are increasingly damaging to the environment, as rising food needs increase the amount of land used and waste, resulting in greenhouse gases. For this reason, research has been started on what sustainable foods can be. The term sustainable food includes providing the food needs of today's people and subsequent generations with minor damage to the environment. This study aims to give examples of sustainable foods and compile studies related to sustainable foods with current data. Food alternatives produced or grown to ensure sustainable living are sustainable. Insects, algae, cultured meat, mycoprotein-Quorn, and more than 2,000 edible species are just a few of these sustainable food alternatives. Some species that pass as insect species used as food today are crickets and mealworms. According to some studies, algae may have antimicrobial, antiviral, and anticancer effects, but their total benefit and toxic properties to the human body are still issues that need to be investigated. Recently, algae are consumed both as food in Japan, Korea, and China and can also be used for other purposes. With cultured meat production, the skeleton of animals is not formed, so more edible parts and waste-free nutrients can be created. Also, cultured meats can eliminate the need for feed production. The main ingredient of Quorn Foods is mycoproteins, a type of fungus. Mycoproteins have been used in foods for over 50 years. Even on the mentioned alternatives, researches are still ongoing, and it is not known which of them is more sustainable. Additionally, studies are continuing how it can be more sustainable.

**Key words:** Sustainability, Food Alternatives, Sustainable Nutrition

## POSTER PRESENTATION

### BAP1 mutations in Glioblastoma

\*Corresponding author e-mail: ali.serce.011998@gmail.com

#### Abstract

BAP1 (Brca-1 Associated Protein 1) gene is around 9 kilobases long and located on chromosome 3. The gene consists of 17 exons and codes the BAP1 protein(90kDa). BAP1 is a carboxy-terminal hydrolase(deubiquitinase) enzyme, and it can work both in the cytoplasm and nucleus. This tumor-suppressing protein is involved in important cellular pathways such as cell cycle, DNA repair, cellular differentiation, and cell death. Mutations of BAP1 were found in many cancers such as uveal malignant melanoma, malignant mesothelioma, renal cell carcinoma, and cutaneous melanoma. Most mutations were found in nuclear signal localization (NLS) regions of the gene, NLS-1 and NLS-2, which are responsible for the protein to translocate to nuclei. Glioblastoma also referred to as grade 4 glioma by World Health Organization is one of the most aggressive cancers in the central nervous system. Every year, around 240,000 cases of brain tumors diagnosed and most of them are glioblastoma. It is observed in middle age people (around 64) but it could be also seen in any age, including children. Even though mutations in various tumors are investigated, very few studies included glioblastoma. In the present study, we examined 5 tumors and 4 blood samples of the glioblastoma patients and 2 non-patient blood sample. The participants went under surgery at Kahramanmaraş Sutcu Imam University between 2022 June and January 2023. We sequenced and analyzed the NSL-1 and NSL-2 coding parts of the gene. Even though we have not found any mutation on NLS-1, we found point mutations on NLS-2 regions in two patients.

**Keywords:** Glial tumors, NLS, gene sequencing

#### Abstract

Ferrocenyl Lawesson Reagent (FcLR), an important member of perthiophosphonic acid anhydrides, has been researched in the last 30 years [1]. The reaction of FcLR with alcohols yields ferrocenyl dithiophosphonic acids (Fc-DTPOA). [2]. Fc-DTPOAs form coordination of four or six complexes with metal salts. [3].

In this study, ferrocenyl dithiophosphonic acids were obtained by the reaction of FcLR with aromatic or aliphatic alcohols. These acids that are known previously [2] were converted to ammonium ferrocenyl dithiophosphonates thereof. New heterobimetallic four-coordinated complexes of these salts with Ni(II) or Cd(II) ions were obtained. All of the compounds were characterized by some spectroscopic methods. The anticancer effects of the compounds were also studied *in vitro*.

**Figure 1.** Synthesis reaction of ferrocenyl dithiophosphonato complexes.

#### Abstract

Dry reforming of biogas is a crucial reaction that utilizes the biogas produced from biomass energy as a feedstock. The advantages of this reaction are mitigating the adverse effects of climate change by utilizing the two major greenhouse gases CH<sub>4</sub> and CO<sub>2</sub> as feedstock, production of hydrogen as a renewable energy carrier and sustainable alternative to fossil fuels, production of syngas with an H<sub>2</sub>/CO ratio almost equal to 1 which is favorable for the production of some valuable chemicals via Fischer-Tropsch synthesis [1]. This reaction is highly endothermic and requires high temperatures to overcome the activation energy of the reaction. Therefore, a catalytic reaction system is required to increase conversion and selectivity, minimize waste, and reduce reaction times and energy demands. Nickel is frequently employed as active metal in catalysts due to its cost-effectiveness and high activity in breaking C-C, C-H, and C-O bonds [2-5]. However, the Ni-based catalysts deactivate as a result of the coke deposition leading eventually to the block of the reactor, the reduction of the catalytic activity, selectivity, and product yield. The two side reactions methane cracking and/or Boudouard (CO disproportionation) reaction are thought to be the main contributors to the coke deposition due to the high C/H ratio of the feedstock in the CO<sub>2</sub> reforming of biogas [6]. As a result, Ni-based catalysts are promoted with other metals to overcome this limitation by the synergic effect between Ni and these metals. Depending on its source and the conditions of the anaerobic digestion process, biogas contains mainly CO<sub>2</sub> and CH<sub>4</sub>, as well as trace amounts of H<sub>2</sub>S, NH<sub>3</sub>, and VOCs [7]. In the presence of H<sub>2</sub>S even at ppm concentrations, besides carbon formation, another severe limitation is the loss of the activity of the catalyst due to sulfur poisoning. Thus, it is crucial to develop catalysts that can endure the harmful impacts of both coke deposition and sulfur poisoning. Despite the abundance of research efforts aimed at improving the stability of catalysts against coke deposition, the same cannot be said for research works focused on increasing the resistance of the catalysts against sulfur poisoning. In the present study, the influence of incorporating Ce, Y, and Mg elements on the activity and sulfur resistance of commercially available alumina-supported nickel catalysts during the dry reforming of the biogas reaction is investigated. Monometallic 8Ni@AL and bimetallic 8Ni-3X@AL catalysts (X= Ce, Y, and Mg) were prepared via wet impregnation route and the catalytic activity tests of the catalysts were carried out in a tubular fixed-bed reactor at 750°C and 1 atm with a total flow rate of 60 mL/min and an equivalent volumetric flow rates of CH<sub>4</sub>, CO<sub>2</sub>, and Ar under 50 ppm H<sub>2</sub>S. The conversion rates of the X-doped catalysts were compared with that of the reference Ni@TAL catalyst. The Y and Ce-promoted catalysts exhibited enhanced activity and stability in the absence of H<sub>2</sub>S. In terms of CH<sub>4</sub> conversion, the Y and Ce catalysts displayed higher initial conversion values compared to the unpromoted Ni@TAL catalyst. Notably, Ni-Y@TAL exhibited the highest initial conversion of 82%. Nevertheless, when H<sub>2</sub>S was introduced at the 29<sup>th</sup> minute of the reaction, the conversion rates of the promoted Y and Ce catalysts experienced a sharp decline, ultimately leading to complete deactivation within just 15 minutes of Time on Stream (TOS). On the other hand, the Ni-Mg@TAL catalyst showed low initial CH<sub>4</sub> conversions compared to 8Ni@AL. The trends of the CO<sub>2</sub> conversion were similar to the CH<sub>4</sub> conversion. All catalysts exhibited CO<sub>2</sub> conversion rates higher than that of CH<sub>4</sub>, with an H<sub>2</sub>/CO ratio below 1. This can be attributed to the simultaneous occurrence of the reverse water-gas shift (RWGS) reaction as a side reaction. Despite the observed low stability of the Ni-Y@TAL and Ni-Ce@TAL catalysts in the presence of H<sub>2</sub>S, these catalysts hold promise for future biogas valorization efforts.

### Abstract

It is thought that existence of supportive environments and communities that will direct people's preference to healthier foods are the main factors in prevention of obesity. According to Turkish Dietary Guidelines, it is reported that total amount of sugar consumed in daily diet should not exceed 10% of total energy, which is naturally present in foods and added during processing of foods. Therefore, products containing natural and artificial sweeteners have started to be used as sugar substitutes in food industry to limit total sugar. In our country and many parts of world, cakes are bakery products that contain added sugar, have high nutritive properties, and are produced in different mixtures and shapes, which are frequently consumed due to their hedonic effect. Cake production and consumption among bakery products ranks 3<sup>rd</sup> after bread and biscuits. Although cakes have high carbohydrate, protein and fat content, they are a poor product in terms of soluble and insoluble fiber, vitamins and minerals. Thus, there are studies to increase the nutritional aspect of cakes by adding dietary pulp and flour obtained from whole grain products in order to increase the quality parameters of cakes. Similarly, there are studies in which sugar and/or fat substitutes are used to reduce high sugar and fat content. Sugar substitutes are used to reduce sugar in cakes or to increase cake quality. Some studies, cakes were produced in which different molasses varieties, sugar grass, stevia extracts, honey dust, sugar alcohols, fruit purees, yacon (*Smallanthus sonchifolius*) syrup, and rare sugars (D-allulose) were used as sugar sources. Although the effects of these products, which are used as sugar substitutes, on physico-chemical, textural and sensory properties of cakes are different, they are generally preferred by consumers. For this reason, it is thought that use of sugar substitutes in food industry should increase.

#### Abstract

Multiple sclerosis (MS) is the leading cause of neurological disability among adults and affects women three times more than men. Among the subtypes of MS, Relapsing-Relapsing MS (RRMS) is the most common, characterized by disease states of remission and relapse, often transitioning to Secondary Progressive MS (SPMS). While the RRMS phase is marked by inflammatory processes, the SPMS phase is marked by neurodegeneration. Scientific evidence indicates that circulating microRNAs (miRNAs) play a significant role in various cellular and physiological functions. miRNAs circulate stably in human blood and are sensitive to processes occurring in the organism. miRNAs have been demonstrated to exert significant effects on MS pathology, with extensive investigations having been conducted and continuing inquiries pursued in this realm. Comprehensive studies on miRNAs exhibiting differing expression levels in male and female patients during the RRMS phase are lacking in the literature. In our study, we employed bioinformatics tools such as GEO2R, Cytoscape, and Morpheus to investigate the differences between remission and relapse disease states of RRMS in male and female subjects. MiRNAs displaying deviant expressions were analysed for both disease states and genders. The results of our investigation reveal that miRNAs with distinct expression levels during the remission and relapse phases of RRMS exhibit gender-specific variations. According to the results that will be obtained from this study, it is believed that specific miRNAs capable of distinguishing MS subtypes can be identified. Furthermore, gender-specific potential biomarkers can be discovered by assessing the shared and non-shared miRNAs between females and males. Additionally, there is potential for the identification of miRNAs that could be implicated in prospective treatment and drug development endeavours.

#### Abstract

Regenerative medicine aims to address disorders caused by infections, inflammation, traumatic injury, and accidents by repairing tissue damage. The Mexican axolotl (*Ambystoma mexicanum*) serves as a main model organism for regenerative medicine. These species can regenerate all their organs and tissues in the case of injury or amputation without developing any sort of scar. In our study, we aim to unlock the mystery of this organism's extraordinary ability to divide by working at in-silico and molecular levels. We used preliminary bioassays to determine which of the proteins that constitute neural regeneration capabilities are more favorable. We identified that the Wnt/ $\beta$ -catenin signaling pathway is one of the most prominent pathways regulating proliferation in Mexican axolotls and that the Wnt-1 is a major functional protein in this pathway. Bioinformatics tools such as Phyre2, HDOCK, and DisEMBL have been used to comprehensively investigate the components of the Wnt/ $\beta$ -catenin signaling pathway synthesized from the apical epidermal cover and their relationship with neural regeneration. Analyses have shown that interactions of Wnt-1 proteins with various vitamins such as vitamin A, vitamin D, and vitamin E can affect this signaling pathway. In this respect, protein-vitamin binding complexes may be important not only in terms of docking scores but also in terms of their effects on signaling pathways. In conclusion, with the increasing relevance of bioinformatics studies, it is possible to understand the mechanism of regeneration more rapidly by developing studies at the molecular level. We believe that our study will contribute to regenerative medicine studies and may provide a different perspective on possible treatment methods.

**Key Words:** *Ambystoma mexicanum*, regeneration, bioinformatics, molecular docking

## POSTER PRESENTATION

### Yenilenebilir kaynaklı poliamid sentezi ve poliamid 6 ile karışımlarının karakterizasyonları

T. Sezgin (<https://orcid.org/0000-0002-0279-6909>), H. Esen (<https://orcid.org/0000-0001-5649-6074>)

#### Özet

Geleneksel plastiklerin çevreye verdiği zarar ve fosil yakıt tabanlı ürünlerde artan maliyetler sonucunda, yenilenebilir kaynaklı polimerler, fosil yakıt bazlı polimerlerin yerine alternatif haline gelmektedir. Ayrıca petrolden elde edilen sentetik polimerler, plastik atık olarak doğaya bırakıldıklarında, toprakta uzun süre parçalanmadığından çevre kirliliğine ve toksik madde birikimine neden olmaktadır. Petrol kaynakları üzerindeki aşırı bağımlılığın, biyolojik kaynaklar ya da yenilenebilir kaynakları kullanarak geliştirilen biyoplastik üretimi ile kontrol altına alınabileceği öngörülmektedir. Biyobazlı polimerler ise yenilenebilir kaynaklardan üretilmektedir. Son yıllarda yapılan çalışmalar doğrultusunda, biyobazlı polimerlerin üretimi önem kazanmakta ve petrol bazlı polimerlerin yerini almalarına yönelik çalışmalar artmaktadır. [1-5] Bu çalışmada; ticari kullanımı olan PA6 içerisine kendi üretimimiz olan bio bazlı poliamid farklı oranlarda eklenmiştir. Bio bazlı poliamid izosiyanat ve dimer acid reaksiyonu ile elde edilmiştir. Elde edilen bio bazlı poliamid %5, 10 ve 15 oranlarında ticari PA6 içerisine katılarak ekstrüde edilmiştir. Yapılan analizler sonucunda eklenen bio bazlı poliamidin termal özelliklerde herhangi olumsuz etki meydana getirmediği ve poliamid 6'nın darbe dayanımı arttırdığı gözlemlenmiştir.

**Anahtar Kelimeler:** Bio bazlı poliamid, dimer asit, PA6, mühendislik polimerleri, yenilenebilir kaynaklar

#### Özet

Bu çalışma ‘‘0900 Ziraat’’ kiraz çeşidinde hasat sonrası yenilebilir kaplama (YK) uygulamasının depolama süresince meyve kalitesine olan etkisini belirlemek amacıyla yürütülmüştür. Hasat edilen meyveler, yenilebilir kaplama materyali uygulanmış meyveler ve hiç uygulama yapılmayan meyveler ile bunların ayrı ayrı modifiye atmosfer paketleme (MAP) ile kombinasyonu olmak üzere 4 gruba ayrılmıştır. Yenilebilir kaplama materyali meyvelere solüsyona daldırma şeklinde uygulanmıştır. Kontrol grubu meyveleri ise sadece saf suya daldırılmıştır. Daldırma işleminden sonra tüm meyveler, fazla suyun süzülmesi için 30 dk oda koşullarında bekletilmiştir. Tüm meyveler 1 gün süresince ön soğutma işlemine tabi tutulmuş ve sonrasında modifiye atmosfer uygulanacak gruba ait meyvelerde ambalajlama işlemi gerçekleştirilmiştir. Tüm uygulamalara ait meyveler 0±0,5 °C sıcaklıkta ve %90±5 oransal nem içeren normal atmosfer koşullarında 45 gün süresince soğuk hava deposunda muhafaza edilmiştir. Araştırmada muhafaza süresince 7 gün aralıklarla, meyve eti sertliği (N), ağırlık kaybı (% g), suda çözünür kuru madde miktarı (%SÇKM), meyve suyu pH’sı, titre edilebilir asitlik (% malik asit), meyve kabuk rengi (L\*,C\*, Hue°), fenolik bileşen (GAE mg/100g), kiraz sapı toplam klorofil miktarı (mg 100g-1 ) gibi kalite özellikleri incelenmiştir. Çalışmada yenilebilir kaplama ve modifiye atmosfer paketleme kombineli uygulama, hasat sonrası ‘‘0900 Ziraat’’ kiraz çeşidinin muhafazasında, özellikle meyve eti sertliği, ağırlık kaybı, kiraz sapı klorofil miktarı, suda çözünür kuru madde miktarı ve meyve kabuk rengi üzerine olumlu sonuçlar vermiştir. Hasattan sonra başlangıç analizlerinde yapılan ölçümlerde 2.69 N olan meyve eti sertliği, 35 günlük muhafaza süresinin sonunda kontrol uygulamasında kontrol uygulamasında 0.97 N, YK+MAP uygulamasında 1.73 N değerinde tespit edilmiştir. Kiraz muhafazasında önemli bir kriter olan kiraz sapı klorofil miktarı hasattan sonra 46.39 mg 100g-1 değerinde, muhafaza süresinin sonunda ise kontrol uygulamasında 19.71 mg 100g-1, YK+MAP uygulamasında 24.61 mg 100g-1 değerinde belirlenmiştir.

**Anahtar Kelimeler:** *Prunus avium*, 0900 Ziraat, Yüzey Kaplama, Soğukta Muhafaza, Kalite

## POSTER PRESENTATION

### Immobilization of $\alpha$ -amylase on clear-epoxy-based photo-curable polymer for industrial use

Garen Karaburun<sup>\*1</sup>, Efe Baturhan Orman<sup>1</sup> (ORCID: <https://orcid.org/0000-0002-8441-4061>), Emrah Çakmakçı<sup>1</sup> (ORCID: <https://orcid.org/0000-0002-2876-7460>), Ayşe Ogan<sup>1</sup> (ORCID: <https://orcid.org/0000-0002-8973-9762>)

<sup>\*1</sup>Marmara University, Science Faculty, Chemistry Department, Istanbul, Turkey.

\*Corresponding author e-mail: [garenkaraburun@gmail.com](mailto:garenkaraburun@gmail.com)

#### Abstract

Enzyme immobilization is a process of physically or chemically attaching enzymes on a solid support or matrix via absorption, covalent binding, affinity immobilization, entrapment. These processes may modify the optimum working conditions of enzymes such as pH and temperature. Immobilized enzymes can be used several times unlike free enzymes in industrial processes. These properties make the immobilization of enzymes a favorable technique to the industry.

$\alpha$ -amylase is a highly specific hydrolytic enzyme that breaks down  $\alpha$ -1,4-glycosidic linkage in starch molecules. As a cofactor  $\alpha$ -amylase has a calcium ion ( $\text{Ca}^{2+}$ ) which stabilizes the three-dimensional structure and works as an allosteric activator. They can be obtained from several sources, such as plants, animals and microorganisms. Amylases account for approximately 30% of the world's enzyme market. It is commonly used in various industries such as food, detergent, paper, textile, clinical and medical, production of fuel alcohol, treatment of waste water. Significantly in the food industry, amylases find numerous uses including; production of glucose, fructose and chocolate syrups, changing texture and volume when baking breads and cakes, production of fermented alcoholic beverages.

In our study,  $\alpha$ -amylase was chemically immobilized to a photo-cured polymeric surface with the intent of creating a rapidly-producible material that is food grade. Photo-curing polymerization technique acquires a quick transformation of a liquid monomer into a solid film. Monomers of the studied polymer are biocompatible and have low toxicity levels. The CLEAR-epoxy-based photo-curable polymer was synthesized and characterized by FT-IR. Immobilization efficiency, effect of pH and temperature on activity, kinetics, reusability and storage stability were determined. According to our results, 27% of  $\alpha$ -amylase was immobilized. Immobilized  $\alpha$ -amylase showed better activity in acidic conditions than free enzymes, with maximum efficiency at pH 6.5. This indicates that  $\alpha$ -amylase immobilized to CLEAR-epoxy-based photo-curable polymer can be utilized in industrial processes with acidic conditions.

**Keywords:**  $\alpha$ -amylase, immobilization, photo-curable polymer, food industry

## POSTER PRESENTATION

### The bovine *MYOD1* p.Gly190Ser polymorphism (rs110708239) and its association with carcass traits in East Anatolian Red cattle and Holstein x Turkish native breeds

Nursen SENTURK<sup>1</sup> (0000-0003-1975-0103),  
Sena ARDICLI<sup>1\*</sup> (0000-0003-2758-5945)

#### Abstract

The genes responsible for myogenic differentiation (*MYOD*) encode transcription factors specific to skeletal muscle development, and they are critical candidates for beef production. The collective understanding of the impacts of the *MYOD1* gene on carcass traits remains relatively restricted within native Turkish cattle breeds. Therefore, we evaluated the effects of p.Gly190Ser (c.568G>A) polymorphism in *MYOD1* gene on carcass traits in East Anatolian Red cattle and Holstein x Turkish native breeds. The genotyping of the SNP within exon 1 of the gene was conducted through the PCR-RFLP technique. Population genetic parameters, encompassing adherence to Hardy–Weinberg equilibrium, heterozygosity, number of effective alleles, and polymorphism information content were computed. We employed information encompassing live weight, hot and chilled carcass weight, dressing percentage, chilling loss, back fat thickness, bone content, and valuable cuts yield. We conducted assessments for both the entire population and within each specific breed. The statistical analysis was performed utilizing the general linear model procedure employing the least squares methodology. The findings demonstrated a dominant prevalence of the BB genotype (~60%), resulting in a remarkably high frequency of the B allele (0.68). The  $\chi^2$  test underscored a significant deviation from Hardy–Weinberg equilibrium for the respective locus ( $P < 0.001$ ). The ANOVA outcomes indicated that *MYOD1* rs110708239 marker does not serve as a robust marker within the examined breeds. We noted a significant association with dressing percentage exclusively within East Anatolian Red cattle ( $P < 0.05$ ). No significant alterations linked to genotype were observed in any of the other phenotypic measurements. This investigation centered on the variability exhibited by the bovine *MYOD1* p.Gly190Ser marker, as well as the potential relationships between the resultant genotypes and carcass characteristics. Although a possible association was identified with dressing percentage, the subsequent association analysis indicated that this marker did not exhibit significant genetic strength within the analyzed Turkish native breeds.

**Keywords:** East Anatolian Red breed, *MYOD1*, carcass characteristics, SNP

\*[faydin@comu.edu.tr](mailto:faydin@comu.edu.tr)

#### Abstract

Berberine (BBR) is named as 9,10-dimethoxy-5,6-dihydro-2H-[1,3]-dioxolo[4,5-g]-isoquinolino[3,2-a]-isoquinolin-7-ylum salt [1]. It is a natural molecule synthesized as cyclic quaternary ammonium salt and is known as a benzylisoquinoline alkaloid isolated from the plant *Coptidis chinensis*. The berberine molecule is found in the barks, leaves and twigs of the various plants such as barberry, Oregon grape and tree turmeric and widely used in traditional herbal medicine drug[2]. It is also as a natural dye and is used to dye wool, leather and wood due to its bright yellow color [3].

In this study, the optimized molecular geometries of the berberine and possible aldehyde form of it were calculated with DFT at the B3LYP/6-311++G(d,p) level. The results of theoretical calculations for two forms are compared in this study.

**Key words:** Berberine, Iminium salt, HOMO-LUMO, DFT calculations

#### Özet

Uzun kodlamayan RNA'ların (lncRNA'lar) düzenlenmesinde meydana gelen bozukluklar, tümör oluşumunun önemli bir bileşenidir. Çeşitli tümörlerde lncRNA taurin yukarı regüle edilmiş gen 1'in (lncTUG1) anormal ekspresyonu rapor edilmiştir; ancak osteosarkomun (OS) ilerlemesinde kesin rolü ve temel hedefleri belirsizliğini korumaktadır. Bu çalışmanın amacı, bioinformatik analiz yöntemleri yardımıyla, osteosarkom patogeneğinde muhtemel rolü olan ve TUG1 uzun kodlamayan RNA'sını hedefleyen miRNA'ların belirlenmesi amaçlanmıştır. TUG1 genin muhtemel miRNA düzenleyicilerinin belirlenmesi amacıyla mirtarbase ([https://mirtarbase.cuhk.edu.cn/~miRTarBase/miRTarBase\\_2022/php/index.php](https://mirtarbase.cuhk.edu.cn/~miRTarBase/miRTarBase_2022/php/index.php), Erişim: 03.09.2023) çevrimiçi hedef tahmin aracı kullanılmıştır. Sonuç olarak yapılan analizler, miR-9-5p ve miR-1299 miRNA'ları tarafından düzenlenebileceğini göstermiştir. Önceki çalışmalar, miR-9-5p ve miR-1299 miRNA'larının osteosarkoma gelişimi ilerlemesinde önemli rolleri olduğunu göstermiştir. Bizde yaptığımız bu çalışmada, miR-9-5p ve miR-1299 miRNA'larının TUG1'in post-transkripsiyonel düzenlenmesi yolu ile osteosarkoma gelişimi ve ilerlemesinde önemli rollerinin olabileceğini gösterdik. Ancak bu sonuçları ileri analizler ve deneyler ile doğrulanması ve desteklenmesi gerekmektedir.

**Anahtar Kelimeler:** Osteosarkoma, TUG1, miRNA

#### Abstract

Construction and Demolition Waste (CDW) is currently seen as one of the most important concerns that national authorities, particularly in Turkey, which is in the process of urban transformation and located in an earthquake zone. The search for alternative secondary raw materials for industries that use wood and its derivatives as raw materials is an important issue with the decrease on forest resources. CDW consists of bulky materials such as asphalt, bricks, wood and plastic. The main purpose of this study is use of waste those obtained by recycling the construction and demolition wood waste (CDWW) in production of cement-bonded particle board (CBPP). For this purpose, alkali treatment was carried out at four different concentrations as 2%, 3%, 5% and %8 NaOH alkaline solutions on the CDWW by using the dipping method. A new cement-bonded particle board design was made using these alkali treated CDWW. The mechanical and physical performance of the produced particle boards were carried out and a recipe that yield the particle board having the best results was determined and a life cycle assessment study was conducted. As the recipes were produced by holding the cement/wood (c/w) ratio stable at 1:2, the best results were obtained from the boards produced with 2% NaOH alkali treated CDWW. The modulus of rupture (MOR), modulus of elasticity (MOE) and density tests were applied to the produced boards in accordance with TS EN 310 and TS EN 323 standard, respectively. The values obtained as a results of MOR, MOE and density test are 10.37 N/mm<sup>2</sup>, 6437.28 N/mm<sup>2</sup> and 1255.12 kg/m<sup>3</sup>, respectively. The experimental outcomes showed acceptable mechanical and physical performance of the developed CBPP in compliance with the required standards. The feasibility of the study was evaluated by conducting LCA studies for the most effective recipe. The global warming potential (GWP) value of the recipe with the best result as a 677,11 kg CO<sub>2</sub> equivalent was found. The results of this study can be considered as an effective roadmap for sustainability in all over the world and in applying secondary raw material CDW management.

**Keywords:** Construction and demolition waste, cement-bonded particle board, recycling, LCA.

#### Abstract

In this study, the effect of using waste glass (WG) as aggregate on cement composite board properties was investigated. The large consumption of aggregates in the cement composite board production process and low quality requirements make the construction industry one of the most promising ways of solving the environmental burden of WG. One of the problems with glass is that the main use applications of it are disposable. WG is non-biodegradable and permanently fills landfills. In 2020, Europe's WG recycling rate was determined to be 79%. On the other hand, Turkey is quite behind in this regard with a recycling rate of 14%. Recycling WG will help conserve natural resources, minimize landfills and save energy. For this purpose, four different particle sizes (0-38, 38-63, 63-90 and 90-212  $\mu\text{m}$ ) of WG were obtained by grinding the WG in a ball mill and sieving it in the following process. In the cement composite board recipes, WG were substituted into the aggregate as 10%, 20% and 50% by weight, for all particle sizes. Modulus of rupture (MOR), water absorption (WA) and dry apparent density tests were carried out on the cement composite boards obtained in accordance with the TS EN 12467 standard. According to the test results, the best outcome was obtained from the recipe using 0-38  $\mu\text{m}$  - 10% glass waste. MOR, density and WA values were found to be 6.26 N/mm<sup>2</sup>, 1401 kg/m<sup>3</sup> and 15.51%, respectively. While MOR value increased by 2.3% compared to the control sample, density and WA values decreased by 1.72% and 9.57%, respectively. The use of WG in the construction industry can provide an environmentally friendly solution to these wastes, as well as providing a sustainable and alternative design opportunity for cement composite boards.

**Keywords:** Waste glass, cement composite, sustainability, recycling

## POSTER PRESENTATION

### Tip 2 diabetes mellitus hastalarında FTO ve PPARG genlerinin metilasyon profillerinin belirlenmesi

### Özet

Tip 2 diyabet (T2DM), genetik duyarlılıklar ve çevresel etkileşimler ve çeşitli genler tarafından yönlendirilen kompleks, metabolik bir hastalıktır. Son zamanlarda sayısı artan çalışmalar diyabetes mellitus (DM) ile epigenetik, özellikle de DNA metilasyonu arasındaki ilişkiyi göstermektedir. Bu çalışmada, klinik olarak tip 2 diyabet (T2DM) tanısı konmuş hastaların periferik kan örneklerinde belirlediğimiz aday genlerden alpha-ketoglutarate dependent dioxygenase (FTO) ve peroxisome proliferator activated receptor gamma (PPARG)'ın metilasyon seviyesini ölçmeyi amaçladık. Çalışmamızda, Endokrinoloji Polikliniği'ne başvuran T2DM hastalardan (43) ve yaş ve cinsiyet uyumlu sağlıklı bireylerden (42) tam kanları alındı. Tam kandan izole edilen genomik DNA örnekleri bisülfid dönüşümünden sonra hedef genlerin metilasyon profili metil spesifik PCR ve jel elektroforez yöntemiyle analiz edildi. İstatistiksel analizler sonrası, FTO genindeki metilasyon durumu T2DM hasta ve kontrol grupları arasında farklılık göstermedi. Diyabetli hastalarda PPARG geninin metilasyon seviyesi kontrol grubuna göre anlamlı derecede yüksek çıktı. PPARG'nin insülin duyarlılığını uyarıcı etkileri göz önüne alındığında, bulgularımız, metilasyon aracılı PPARG gen ekspresyonunun baskılanması diyabetli hastalarda insülin direncinin artmasına neden olabileceği ihtimalini güçlendirmektedir. PPARG genindeki metilasyonun T2DM hastalarındaki etkilerini ve hastalıkla ilişkisini daha iyi anlayabilmek için, daha büyük hasta popülasyonu ve kantitatif metodlar kullanarak ileri gen ekspresyon çalışmaları gerekli olacaktır.

**Anahtar kelimeler:** Tip 2 diyabetes mellitus, DNA metilasyonu, PPARG, FTO.

## POSTER PRESENTATION

### Silika esaslı ilaç taşıyıcı sistemlerin geliştirilmesi

Ecem Ünsal\* (ORCID: <https://orcid.org/0000-0001-7534-3030>),  
Müjgan Okur (ORCID: <https://orcid.org/0000-0002-1533-9408>)

#### Özet

İlaç salım sistemleri kimyasal bir uyarıya cevap olarak ilacın serbest bırakıldığı sistemlerdir. Kontrollü ilaç salım sistemleri ise ilaç etken maddenin bölgesel veya sistematik olarak önceden belirlenmiş oranlarda ve spesifik zaman aralıklarında salım yapmasını sağlar. Kontrollü salım sistemlerinin temel hedefi, kan plazma konsantrasyonundaki ilaç etken madde miktarını sabitlemektir. Kontrolü ilaç salım sistemleri; pH, iyonik kuvvetler, enzim gibi fizyolojik koşulları oluşturan faktörlerden etkilenmektedir. Kontrollü ilaç salım sistemlerinin tedavi edici oranda ilaç düzeyinin sürekli korunması, hedeflenebilmesi nedeniyle zararlı etkilerin azaltılması, gerek duyulan ilaç miktarının azaltılabilmesi, önerilen ilaç rejimine hastanın uyumunu geliştirecek şekilde dozaj miktarının azaltılabilmesi, kısa yarılanma ömrüne sahip ilaçlar (örneğin proteinler ve peptid ilaçlar) için ilaç yönteminin kolaylaştırılması gibi avantajları bulunmaktadır. Kitosan, polietilen oksit, polikaprolakton, aljinat gibi polimerler, montmorillonit, haaloysite gibi killer, silika, selüloz gibi bazı malzemeler ilaç taşıyıcı destek malzeme olarak kullanılabilir. Silika son zamanlarda kullanılan ve tıbbi uygulamalar için umut verici bir malzemelerden birisidir. Silika tetraetilortosilikat (TEOS) ve tetrametilortosilikat gibi alkoksisilanlar kullanılarak hazırlanabildiği gibi şeker kamışı küspesi, pirinç kabuğu, mısır koçanı, kahve kabuğu ve buğday kabuğu gibi biyokütlelerden de hazırlanabilmektedir. Doğal kaynaklardan elde edilen silika, düşük maliyetli olması, çevre dostu olması ve kolay elde edilebilirliği nedeniyle biyomedikal ve malzeme alanlarında kullanım alanı bulmaktadır. Bu çalışmada kullanılan silika, yaklaşık %90 oranında silika içeren çeltik artıkları külünden elde edilmiştir. Çeltik külü NaOH ile işleme tabi tutularak silika ekstraksiyonu gerçekleştirilmiş, daha sonra süzülerek sıvı kısım HCL ile nötralize edilmiştir. 1 gün yaşlandırma işlemi uygulanan silika süzülerek saf su ile iyice yıkanmış, çözücü değişimi basamağından sonra dondurarak kurutma yöntemiyle kurutulmuştur. Bu şekilde hazırlanan malzemeye emdirme yoluyla ilaç yüklenmiş ve bu şekilde hazırlanan ilaç yüklü malzemenin ilaç salım özellikleri incelenmiştir. Çalışmada kullanılmayı planlanan ilaç deksketoprofen trometamol olup, nonsteroid antiinflamatuvar bir ilaçtır. İlaç salım deneyleri 37 °C sıcaklıkta, 100 rpm karıştırma hızında, pH 7.4 fosfat tamponu ortamında ve kesikli sistemde gerçekleştirilecektir. İlaç salım oranlarının belirlenebilmesi için deney ortamından belli aralıklarla örnekler alınmış, salınan ilaç miktarı UV spektroskopisi cihazında 260 nm dalga boyunda absorbanları ölçülerek belirlenmiştir.

**Anahtar Kelimeler:** Çeltik, deksketoprofen, ilaç salımı, silika

**Teşekkür:** Bu çalışma Gazi Üniversitesi Bilimsel Araştırma Projeleri Koordinasyon Birimi (BAP) (FYL-2022-7760) tarafından maddi olarak desteklenmektedir.

#### Özet

Gıdaların mikroorganizmalar tarafından bozulması, henüz tam olarak çözülememiş dünya çapında bir sorundur. Gıdaların saklanması için, uygun bir çözüm hem ekonomik açıdan hem de insan sağlığı açısından faydalı olacaktır. Gıdayı güvenli hale getirmenin ve ona doğal veya 'çevre dostu' bir imaj vermenin yeni yollarına ilgi artmıştır. Gıdaların raf ömrünü uzatmak ve güvenli gıda sağlamak için gıda muhafazası, gıda endüstrisinin ve devlet kurumlarının en önemli endişelerinden biridir. Domates bazlı yemeklik ürünler için koruyucu olarak kullanılan sorbik asit-potasyum sorbat, benzoik asit-benzoatlar gibi koruyucuların yasaklanması planlanmaktadır. Son yıllarda, raf ömrünü uzatmak için gıdaların muhafazasında esansiyel yağların kullanımına ilişkin başarılı araştırmalar yapılmıştır.

Bu çalışmada, kimyasal koruyuculara alternatif olabilecek, %99 sinamaldehit içeren tarçın yağının yeni nesil gıda koruyucusu olarak kullanımı hedeflenmektedir. İzole soy protein, kitosan ve gum arabik ile kompleks koaservasyon yöntemiyle enkapsüle edilmiştir. Enkapsüle edilen formülasyonların, enkapsülasyon verimi (EE), yükleme kapasitesi (LC) ve partikül boyutları karakterize edilmiştir. İzole soy protein / kitosan kompleks koaservasyonu %97,08 (EE) ve %45,30 (LC) ve izole soy protein / gum arabik kompleks koaservasyonu % 82,83 ve % 52,01 (LC) ölçülmüştür.

Bozulmuş salça örneklerinden izole edilen, *Aspergillus japonicus isolate D02* ve *Aspergillus flavus isolate 26* izolatlarına karşı antifungal etkinlikleri, spot kültür büyüme inhibisyonu (SPOTi) tahlili ve mikrotitre plakası (mikrodilüsyon) biyoanalizi iki yöntemle test edilmiştir. İzole soy protein / kitosan kompleks koaservasyonu MIC (minimal inhibisyon konsantrasyonu) ve MFC (minimal fungisidal konsantrasyonu) sırasıyla 187,5 ppm ve 62,5 ppm; izole soy protein / gum arabik kompleks koaservasyonu 125 ppm ve 250 ppm olarak tespit edilmiştir.

**Anahtar Kelimeler:** Enkapsülasyon, Kompleks koaservasyon, Antifungal aktivite

## POSTER PRESENTATION

### Cyclotetraphosphazene-based Hg(II) and Zn(II) coordination compounds

#### Abstract

Cyclophosphazenes are inorganic heterocyclic rings that contain alternating phosphorus and nitrogen atoms in the ring skeleton [1]. They show versatile coordination behaviour, particularly in the form of multidentate ligands carrying additional exocyclic donor functions [2]. Due to their easily functionalization, flexibility, and stability, cyclophosphazenes have significant interest to researchers [3]. Especially, trimer ( $N_3P_3Cl_6$ ) and tetramer ( $N_4P_4Cl_8$ ) have been the most striking structures [4]. Cyclophosphazenes are their versatility as ligands owing to ring flexibility and bonding groups, so they easily interact with transition metal ions [3,4]. Imidazole is a typical heterocyclic molecule which features a five-membered ring structure consisting of three carbon atoms and two nitrogen atoms. The nitrogen atoms are located at the first and third positions in the ring. Imidazole and its derivatives have been found to exhibit favourable ligand properties in the formation of metal complexes [5].

In this study, fully substituted cyclotetraphosphazene ligand with 2-isopropylimidazole reacted with  $HgCl_2$  and  $ZnCl_2$  salts, respectively. As a result, two new coordination compounds were obtained, and their structures were determined by single crystal X-ray diffraction method.

**Keywords:** Cyclotetraphosphazene, isopropyl imidazole, coordination compounds.

We would like to thank the project numbered TUBITAK-121Z236 for its financial support.

#### Abstract

Various anthropological activities (agriculture, urbanization, industry, etc.) cause many harmful pollutants spreading into the environment. Among many toxic chemicals, dyes are the most dangerous organic pollutants. Biological treatment is based on the use of microorganisms with bioremediation capabilities in the treatment process. In this study, the mixed microalgal and cyanobacterial culture was obtained from hot spring of Denizli. The bioremediation capacity of mixed culture in media with Setazol Black B, Setazol Blue BRFX, and Setazol Navy Blue SBG textile dyes was determined. After selection of the pollutant, experiments were conducted in BG11 media at pH 8, with 8.7 mg/L Setazol Navy Blue SBG, and biomass concentrations [10% and 20% (v/v)]. The amount of dye remaining in the medium was determined spectrophotometrically. The highest bioremediation occurred in a medium containing 8.7 mg/L SNB dye with 10% (v/v) biomass, achieving 98.9% efficiency at the end of a 6-day incubation period.

**Keywords:** microalgae; cyanobacteria, textile dye; bioremediation

#### Abstract

Nanofibers are fine porous structures with average fiber diameters of one micron or less. As the fiber diameter decreases, the physical, biological and chemical properties of the fibers improve and properties such as large surface area, porosity and high permeability are obtained. In addition to tissue engineering, biomedical and regenerative medicine applications, in the field of pharmacy, nanofibers have found the opportunity to be used in many areas with the developing nanotechnology due to their features such as high surface/volume area, ease of application and low cost. Although there are many methods in nanofiber production, the most prominent method in recent years is the electrospinning method. It is based on the accumulation of the filaments coming out of the jets created by the electric field caused by the voltage applied to a polymer solution, on the collector plate. Although nanofibers produced by electrospinning technologies have gained a place in the market in many areas, there are many problems that need to be solved to ensure permanent stability in industrial production. In this study, the advantages and disadvantages of needle and needleless electrospinning methods in production will be examined and their suitability for scale-up will be investigated. Although the needle electrospinning method has advantages such as easy installation, low voltage requirement, relatively uniform fiber diameter, it has disadvantages such as clogging of the needles, inhomogeneous solution feeding rate and more irregular electric field. The needleless electrospinning method has advantages such as easy sustainability, no needle clogging problems, and higher efficiency. But, it has disadvantages such as the need for higher voltage and the difficulty of maintaining the viscosity and concentration of the solution. Although industrial devices are available for large-scale production of both methods, optimization of process parameters is very important for product optimization.

**Keywords:** Electrospinning, nanofiber, needle electrospinning, needleless electrospinning,

## POSTER PRESENTATION

### Zeytin yapraklarından ekstrakte edilen toplam fenolik bileşiklerin miktarına kurutma ve ekstraksiyon parametrelerinin etkisi

\*Sorumlu yazar e-mail: meldacebbar@gmail.com

### Özet

Fenolik bileşikler açısından oldukça zengin olan zeytin yaprakları günümüzde pek değerlendirilmemektedir. Genellikle yakılmakta, toprağa gömülmekte ya da hayvan yemi olarak kullanılmaktadır. Yapraklar sürdürülebilirlik açısından, biyoaktif özellikleri nedeniyle katma değeri yüksek ürünlerin geliştirilmesinde kullanılabilir ucuz, kolay erişilebilir bir hammadDEDİR. Bitkilerden ekstrakte edilen fenolik bileşiklerin miktarı kurutma, saklama ve ekstraksiyon yöntemlerine bağlıdır. Bu nedenle bu değerli bileşiklerin eldesinde optimum değerler birçok bağımsız değişkenin birbirleriyle olan ilişkilerinin de değerlendirilebileceği dENEYSel tasarım yöntemi ile belirlenmeli ve zamandan tasarruf sağlayarak endüstriye katkı sağlanmalıdır. Literatürde zeytin yapraklarına kurutma veya ekstraksiyon parametrelerinin toplam fenolik bileşiklerin miktarına etkisinin incelendiği çalışmalar olmasına rağmen, kurutma ve ekstraksiyon parametrelerinin birlikte değerlendirildiği ve kurutma kinetiğinin incelendiği çalışmalara pek rastlanmamaktadır. Bu nedenle zeytin yapraklarından ekstrakte edilen toplam fenolik bileşiklerin miktarına kurutma ve ekstraksiyon parametrelerinin etkileri, Box-Behnken dENEYSel tasarım yöntemi kullanılarak birlikte değerlendirilmiştir. Bu çalışmada, Balıkesir ili Edremit ilçesinden temin edilen zeytin yaprakları farklı çıkış güçlerinde mikrodalga fırında kurutulmuş ve yapılan matematiksel modelleme çalışmalarında kurutma kinetiği için Page modelin yüksek oranda uygunluk gösterdiği görülmüştür. Kurutma işlemleri sonrasında Box-Behnken dENEYSel tasarım yöntemi ile 3 faktörlü (mikrodalga çıkış gücü, etanol oranı, zaman), 3 seviyeli ve yanıt olan toplam fenolik bileşenlerin miktarını belirlemek için tasarım yapılmıştır. Merkez noktada 5 tekrarlı deney ve toplam 17 deney gerçekleştirilmiştir. Ekstraktların toplam fenolik bileşiklerin miktarı UV spektrofotometre ile belirlenmiştir. Deney sonuçlarını optimize edebilmek için ANOVA analizi gerçekleştirilmiş ve deney sonuçlarına kuadratik modelin uygunluğu görülmüştür. Analize göre deney koşullarının ekstrakte edilen toplam fenolik bileşenlerin miktarına etkisi; güç ve zaman lineer terimlerde anlamlı ( $p < 0,05$ ) iken etanol oranının tek başına önemli bir faktör olmadığı kuadratik ve interaksiyon terimlerinde etkili olduğu görülmektedir.

**Anahtar Kelimeler:** Zeytin yaprağı, fenol, kurutma kinetiği, ekstraksiyon, Box-Behnken

**Teşekkür:** Bu çalışma Yıldız Teknik Üniversitesi Bilimsel Araştırma Proje Koordinatörü (proje numarası FYL-2023-5679) tarafından desteklenmektedir.

## POSTER PRESENTATION

### Taze gül (*Rosa damascena*) ve posasının toplam fenolik bileşiklerinin miktarına hasat döneminin etkisi

Melda Cebbar<sup>1\*</sup> (ORCID: 0009-0007-8696-3850), Özlem Doğan<sup>2</sup> (ORCID: 0000-0002-1815-7239)

<sup>1</sup>Yıldız Teknik Üniversitesi, Kimya Metalurji Fakültesi, Kimya Mühendisliği Bölümü, Davutpaşa Kampüsü, 34220 İstanbul, Türkiye

<sup>2</sup>Yıldız Teknik Üniversitesi, Kimya Metalurji Fakültesi, Biyomühendislik Bölümü, Davutpaşa Kampüsü, 34220 İstanbul, Türkiye

\*Sorumlu yazar e-mail: meldacebbar@gmail.com

#### Özet

*Rosa damascena*, Rosaceae familyasının Rosa cinsinde bulunan en önemli türlerinden birisidir. Güzel kokusu ile parfümeri sektöründe ve ayrıca yapısındaki fenol bileşiklerinin sayısının çokluğundan farmakolojik, kozmetik vb. alanlarda pozitif etkileri ile uzun yıllardır kullanılmaktadır. Dünyada öncelikle Türkiye, İran, Bulgaristan, İtalya, Rusya'nın güneyi, Hindistan, Çin ve Libya'da yetiştirilmektedir. Ülkemizde en fazla Isparta'da yetiştirilen *Rosa damascena* hasadı mayıs ortasından haziran ortasına kadar yaklaşık bir ay, senede bir kere gerçekleşmektedir. Türkiye'de yaklaşık 10000 ton *Rosa damascena* çiçeğinden gül yağı, gül suyu, gül absolütü ve gül konkreti üretilmektedir. Özellikle koku endüstrisinde yaygın olarak kullanılan gülün 4 tonundan 1 kilogram gül yağı elde edilmesinden dolayı oldukça değerlidir. Bu nedenle, gül yağının miktarını ve kalitesini artırma, kokusunun hangi ekstraksiyon ve saklama koşullarında daha iyi olduğunu belirlemek adına yapılan çalışmalar literatürde yaygındır. Fakat bu gül ürünleri üretimi sonucunda açığa çıkan doğal fenol kaynakları olan posaların atık olmaktansa endüstriler açısından değerlendirilmesi için elde edilme sürecinin optimum koşullarını belirlemek literatür açısından eksik kalmıştır. Bu çalışmada, Ispartadan 2022 yılı hasat döneminin başında ve sonunda toplanmış taze gül ve bu güllerin hidrodistilasyon işlemiyle işlenerek açığa çıkan gül posasının yapısındaki toplam fenolik madde miktarına hasat döneminin etkisi incelenmiştir. En yüksek toplam fenolik madde miktarına ilk hasat taze gül ile ulaşılmıştır son hasatta ise toplam fenolik madde miktarında biraz düşüş görülmüştür. İşlenmiş gül distile posalarının ekstratlarındaki toplam fenolik madde miktarına bakıldığında, en yüksek değere yine ilk hasatta elde edilen posaların ekstratlarında ulaşılmıştır. Deney sonuçları değerlendirildiğinde hasat döneminin az da olsa güldeki toplam fenolik madde miktarını etkilediği görülmüştür. İşlem görmüş gül posasının da hala yüksek oranda fenol içerdiği belirlenmiştir.

**Anahtar Kelimeler:** *Rosa damascena*, posa, fenol, ekstraksiyon

**Teşekkür:** Çalışmada kullanılan gülleri ve gül posalarını sağlayan Gülsha Kozmetik Sanayi ve Ticaret A.Ş.'ye teşekkür ederiz.

## POSTER PRESENTATION

### Synthesis and Characterization of Tadpole-Like Single-Chain Nanoparticles as Polymer-Drug Conjugates

Hatice Kübra Batu<sup>1</sup>(<https://orcid.org/0000-0002-1287-7550>),

#### Abstract

Nanotechnology is focused on the development of synthetic techniques for producing nanoscale objects that enable precise size control and specific functionalization. For that purpose, single-chain polymer nanoparticles (SCNPs), created by the collapse or folding of polymer chains into structurally defined nanoparticles, are a dramatically growing research topic in polymer science that has been developing over the last twenty-five years. SCNPs, which are ultra-small cross-linked nanoparticles, are obtained by individual folding or collapse of linear polymer chains through in-chain cross-linking under high dilution conditions. SCNPs allow the formation of polymer nanoparticles, which are much smaller than traditional polymer nanoparticles, 1-20 nm in size. Curcumin (Cur), a polyphenolic compound derived from *Curcuma longa* L., is known to have various therapeutic effects including anti-inflammatory, antiproliferative, antioxidant and antiangiogenic activities. Although many studies have showed the high anticancer potential of Cur, its bioavailability has been found to be low due to its poor absorption and rapid metabolism. These problems have been tried to be overcome with the use of nanocarriers.

In this study, we aimed to design tadpole-like single-chain nanoparticles as polymer-drug conjugates. A poly(ethylene glycol) (PEG) based macroRAFT agent was synthesized and used for the reversible addition-fragmentation chain-transfer (RAFT) polymerization of methyl methacrylate (MMA) and methacrylic acid (MAA) monomers. MAA units of obtained amphiphilic copolymers were then reacted with Cur in a dilute solution to obtain tadpole-like single-chain nanoparticles. The polymers and SCNPs were characterized by FT-IR, GPC, DSC, UV-Vis, <sup>1</sup>H NMR and DLS analyses.

**Keywords:** Amphiphilic copolymers, reversible addition-fragmentation chain-transfer (RAFT) polymerization, single-chain polymeric nanoparticle (SCNP), curcumin.

#### Abstract

Melanin plays self-protective roles among bacteria, fungi, plants, animals, and humans. These roles include blocking of UV radiation, toxic iron chelation, and buffering against environmental conditions. Melanin can be synthesized from L-tyrosine through various enzymatic and non-enzymatic routes. A number of bacterial hosts, including *Streptomyces* and *Bacillus* species, have been used for the production of melanin, but the yield was not high enough for large-scale production. One route commonly employed by bacteria uses tyrosinase enzymes. This enzyme converts L-tyrosine to (3,4-dihidroksi-L-fenilalanin) L-DOPA. The same enzyme converts L-DOPA to L-dopaquinone, which is then non-enzymatically converted to L-dopachrome. Finally, L-dopachrome is polymerized to the black-brown pigment melanin. This work uses the Cu<sup>+2</sup>-dependent *Ralstonia solanacearum* tyrosinase enzyme for the efficient production of melanin in *Corynebacterium glutamicum* as the host. The industrial workhorse *C. glutamicum* has many advantages such as fast growth and genetic stability; it can reach high cell densities. To this end, *C. glutamicum* EKV-I has been used. This strain requires external L-tyrosine (1 g/L) addition which was converted to L-DOPA and finally polymerized to melanin. Here, melanin production was maximized by optimizing agitation speed, Cu<sup>+2</sup> concentration, and production volume in a given flask. HPLC was used to confirm melanin synthesis. Then, melanin concentration was determined via measuring OD<sub>400</sub> value. This value was converted to the dry cell weight using the correlation, 1 OD<sub>400</sub> = 0.066 g/L. The optimum conditions for melanin production with EKV-I were in a 50 mL growth volume in a 500 ml flask agitated at 150 rpm for 48 hours. The concentration of Cu<sup>+2</sup> was adjusted to 0.1 mM initially. The obtained yield was 0.75 g/L of melanin with 1 g/L of L-tyrosine. The authors acknowledge Tubitak BİDEB 2210D, Tubitak 120N728, and FYL-2023-10911 for support.

**Keywords:** Melanin, eumelanin, *C. glutamicum*, L-DOPA, L-tyrosine

#### Abstract

The industrial use of metals and organic dyes is widespread. Insufficient treatment of wastewaters can result in the release of dangerous materials, which can adversely affect the soil and aquatic life. Wastewaters including such pollutants have to be treated. In wastewater treatment, chemical and biological methods can be used. Chemical methods offer an alternative solution, they prove unfavourable due to their high cost and the secondary by-products they generate in large-scale treatment systems. Biological methods, on the other hand, are preferred in the first place because they require almost no chemicals and are easy to intervene in. In these methods, microorganisms capable of bioremediation are used. For this purpose, the mixed microbial culture was obtained from Çubuk stream (Ankara). Trials were done in media containing different heavy metals and Setazol Navy Blue SBG (SNB). Experiments were conducted with regards to pH levels, initial pollutant, and biomass concentrations. Mixed microbial culture had the maximum bioremediation capacity in media with Cr(VI)+SNB.

**Keywords:** bacteria, mixed culture, dye, heavy metal, bioremediation

#### Abstract

This paper addresses the critical problem of antibiotic resistance and the need for alternative antibacterial strategies. It focuses on the application of nanomaterials with different dimensionalities (0-D, 1-D, 2-D, and 3-D) in antibacterial contexts. The article explores the unique properties and mechanisms of low-dimensional nanomaterials like silver nanoparticles (AgNPs) and graphene quantum dots (GQDs) in fighting bacterial infections. These nanomaterials offer promise in wound dressings, medical implants, and food packaging, delivering clinical benefits while minimizing side effects.

This research explores the potential of  $\beta$ -rhombohedral crystalline structured borophene nanosheets as multifunctional antibacterial and antifungal agents. Prepared via physical exfoliation, these nanosheets exhibit significant inhibitory activity against pathogenic microorganisms, including *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Escherichia coli*, *Candida albicans*, and *Aspergillus brasiliensis*. The study suggests that borophene nanosheets, with their unique physicochemical properties, hold promise as effective antimicrobial coatings in biomedical and packaging applications, offering a novel solution to combat bacterial and fungal infections.

**Keywords:** antimicrobial, antifungal, borophene, microorganisms, nanosheets.

### Özet

Suyun toprak, kaya gibi yer altı kaynaklarıyla temas etmesi sonucu  $Ca^{+2}$  ve  $Mg^{+2}$  iyonlarının çözünmesi su sertliğini oluşturur. Oluşan su sertliği ise endüstride kullanılmadan önce suyun işlem görmesini zorunlu hale getirmektedir. Her sanayi dalının kullandığı su miktarı ve sudan beklediği özellikler farklı olabilmektedir. Ancak su sertliği bütün endüstriyel uygulamaları etkileyen önemli bir parametredir. Su tüketim oranının yüksek olduğu tekstil sektöründe su içerisinde bulunan ve suya sertlik veren  $Ca^{+2}$  ve  $Mg^{+2}$  iyonları tutulmadıkları takdirde kumaş üzerinde lekelenmeye sebep olmaktadır. Bu lekelenme kumaşların renginde solma, dokusunda kalınlaşma gibi sorunlara yol açarak kumaşların estetik yapısını bozmaktadır. Bu sorunlar ancak kumaşların tekrar durulanmasıyla bertaraf edilebilir. Tekrar durulanma prosesi ise ekstra su sarfiyatına neden olmaktadır. Pek çok endüstriyel uygulamada kullanılan buhar kazanları, soğutma sistemleri gibi ekipmanlar sert suyun neden olduğu kireç birikintileriyle zarar görebilir. Ekipmanların bakım ve kullanım süresini uzatmak için su sertliği kontrol edilerek belirlenen seviyelerde tutulmalıdır. Çalışmamız kapsamında geliştirilen Akrilik / Maleik kopolimeri suya sertlik veren  $Ca^{+2}$  ve  $Mg^{+2}$  iyonlarıyla şelat oluşturarak bu iyonları ortamdaki uzaklaştırabilmektedir. Su sertliği kontrol altında tutulduğunda veya önlendiğinde su kaynaklarının korunması, ekipmanların ömrünün uzatılması ve enerji tasarrufu konularında fayda sağlanacaktır. Geliştirmiş olduğumuz kopolimer aynı zamanda sahip olduğu dispersiyon kabiliyetiyle de yıkama sırasında tutunduğu yerden koparılan kirliliklerin dispersiyon halinde su ile uzaklaşmasını sağlamaktadır. Boya endüstrisinde ise pigmentlerin tanecik boyutlarının ve yapı sektöründe kalsit taneciklerinin küçültülmesinde katkı malzemesi olarak kullanılmaktadır.

Geliştirmiş olduğumuz ürünle benzer özelliklere sahip olan fosfat türevli ürünlerin çevreye çok ciddi boyutta zararları bulunmaktadır. Toplumun çevre konusunda duyarlılığının artması sonucunda geliştirmiş olduğumuz ürünün muadillerine göre çevreye daha az zarar veren çevre dostu bir yapıya sahip olması tercih sebebi olmaktadır ve muadillerine göre avantaj sağlamaktadır. Geliştirilen Akrilik / Maleik kopolimeri başta su sertliğinin önlenmesi ve azaltılması olmak üzere deterjan, tekstil, deri, yapı kimyasalları, su şartlandırma gibi birçok sektörde ve yaşamın farklı alanlarında yardımcı kimyasal olarak önemli bir yer edinmiştir.

**Anahtar Kelimeler:** Akrilik / Maleik kopolimeri,  $Ca^{+2}$  ve  $Mg^{+2}$  iyonları, çevre dostu, dispersiyon, su sertliği, şelat

Şekil 1: Akrilik/maleik kopolimer

#### Abstract

There are many factors that affect fruit juice quality. Considering the widespread consumption in our country and around the world, determining these quality criteria is of great importance in terms of food safety and human health. Hence, in this study, the aim was to determine quality criteria such as pH, Brix, electrical conductivity, total phenolic content, and the amount of furfural compounds in fruit juices. Total 100 samples, 4 different fruit juice samples (pineapple, apple, pomegranate, grape) and turnip juice sample from seven different brands (A, B, C, D, E, F, G) were analyzed. Furfural compounds in the fruit juices were analyzed using high-performance liquid chromatography with a diode array detector. In the analysis of 5-hydroxymethylfurfural (5-HMF) and furfural, linear results (5-HMF:  $R^2 > 0.999$ ; furfural:  $R^2 > 0.999$ ) were obtained over a wide concentration range. The average recoveries of 5-HMF and furfural were found as 109.1% and 98.5%, respectively. The limit of detection and the limit of quantification values for 5-HMF were determined as 0.0153 mg/L and 0.0463 mg/L, respectively. The limit of detection and the limit of quantification values were also determined as 0.0136 mg/L and 0.0413 mg/L for furfural. The mean 5-HMF values in pineapple, apple, pomegranate and grape juices were found as  $0.054 \pm 0.034$  mg/L,  $0.052 \pm 0.056$  mg/L,  $0.661 \pm 0.451$  mg/L,  $0.092 \pm 0.047$  mg/L, respectively. The amount of 5-HMF in turnip juice was determined as  $0.003 \pm 0.003$  mg/L. The mean furfural values in pineapple, apple, pomegranate and grape juices were found as  $0.007 \pm 0.004$  mg/L,  $0.006 \pm 0.008$  mg/L,  $0.087 \pm 0.059$  mg/L and  $0.012 \pm 0.006$  mg/L, respectively. Furfural could not be detected in turnip juice. The highest total phenolic content (TPC) were determined in pomegranate juice ( $399.867 \pm 149.795$  mg/L), the lowest TPC values were determined in pineapple juice ( $49.307 \pm 16.536$  mg/L). Other parameters such as pH, electrical conductivity, brix were generally determined in accordance with the standards.

**Keywords:** 5-HMF, Furfural, Total Phenolic Content, Non-Alcoholic Drink, HPLC

#### Abstract

Lignocellulosic biomass is a potential source of sugars such as glucose and xylose which can be converted to value-added chemicals via microorganisms. Additionally, it also contains essential constituents for cell growth. In typical weather conditions, Turkey annually generates roughly 600,000 metric tons of hazelnuts, accounting for approximately 75% of the global production. This results in an equivalent amount of hazelnut husk waste which is often discarded and it is not harnessed for alternative purposes. In this work, the focus was to extract fermentable sugars and other essential components from hazelnut husk for L-tyrosine production in *Corynebacterium glutamicum*. *C. glutamicum* serves as the backbone of white biotechnology on an industrial scale, playing a pivotal role in the annual production of millions of tons of amino acids. L-tyrosine is among the three aromatic amino acids of protein biosynthesis. It is also the precursor of metabolites with defense, neurotransmitter, UV protectant, analgesic, and antioxidant functions that find applications in food, pharmaceutical, chemical and cosmetic industries. To release fermentable sugars from hazelnut husk, 50 g of dried hazelnut husk powder was suspended in 400 mL 3.8 % sulfuric acid and autoclaved for 50 minutes. Then, liquid fraction was collected by filtering and pH was adjusted to 7.0. The sugar content of the hydrolysate was 2±0.3 g/L of glucose and 8±0.6 g/L of xylose. Resulting hydrolysate was sterilized via autoclaving for growth and production. In order to determine the optimum growth conditions in 96-well plates, different amounts of hydrolysate were tested. Then, hydrolysate was tested for L-tyrosine production in 500-mL flasks for 72 hours. Results indicated that cells can efficiently grow and produce 277 mg/L L-tyrosine on pure hydrolysate without any supplementation. Although more biomass accumulated on higher hydrolysate amounts, this also prolonged the lag phase. Financial support by 120N728 and FYL-2023-10995 is gratefully acknowledged.

**Keywords:** L-tyrosine, *C. glutamicum*, Agro-waste, Bioproduction, Feedstock

#### Abstract

Lung infections caused by various pathogens are defined as the damage in the lung. Although the severity of the damage may vary from mild to life threatening, burden of the disease is considered greater than other diseases which are well-recognized. Since pathogens causing lung infections, some of which are methicillin-resistant *Staphylococcus aureus*, *Pseudomonas aeruginosa* and *Klebsiella pneumoniae*, are becoming resistant to antibiotics worldwide, postbiotics as new and safe natural compounds that are beneficial to host, have gained attention as an alternative to antibiotics. The present study aimed to evaluate the anti-microbial and antioxidant activities of postbiotics derived from *Lactobacillus murinus* isolated from the lung microbiota of Spalax spp., which have unique lung microbiota due to their hypoxic and hypercapnic living conditions. For this purpose, lung tissue samples aseptically obtained from Spalax sp. were placed in MRS broth for pre-enrichment. Following pre-enrichment, bacteria were isolated using pour plate method. Postbiotics were extracted from the isolates by centrifugation and filtration, and their anti-microbial activity was tested against MRSA, *P. aeruginosa* and *K. pneumoniae* by agar well diffusion method. Moreover, antioxidant activity of postbiotics were determined by investigating total phenolic and flavonoid content, as well as their effectiveness in eliminating DPPH radical. According to our results, postbiotics from *Lactobacillus murinus* displayed strong anti-microbial activity against all pathogens tested. Inhibition zones were measured as  $13 \pm 0.4$  mm,  $11 \pm 0.5$  mm,  $13 \pm 0.2$  mm for *K. pneumoniae*, MRSA and *P. aeruginosa*, respectively. Total phenolic content was determined as 7 mg GAE/g while total flavonoid content was calculated as 6.52 mg/g QE. DPPH radical scavenging activity of postbiotics was found to be 100% efficient for all concentrations tested. These findings suggest that postbiotics derived from *L. murinus* isolated from lung microbiota of Spalax spp. may be used as an alternative to antibiotics.

**Keywords:** Lung microbiota, Postbiotics, Lung infections

### Özet

D vitamini günümüzde gittikçe önem kazanan bir mikro besin olup, vücutta progesteron hormonuna benzer şekilde etki gösterdiği literatürde yer almaktadır. D vitamini eksikliğinin ovaryum dokusundaki etkileri üzerine çalışmalar daha çok polistik over sendromu ve preeklampsiyi kapsamaktadır. Gebeliğin erken döneminde ovaryum histolojisi üzerine yapılan çalışmalar oldukça sınırlıdır. Çalışmamızın amacı, D vitamini eksikliği modeli oluşturulmuş, gebeliğin erken dönemindeki dişi sıçan ovaryum dokularında oluşan hasarın, histomorfolojik düzeyde etkilerini inceleyerek ortaya koymaktır. Bu amaçla, 12 adet 4 haftalık, Sprague-Dawley albino cinsi dişi sıçan iki gruba ayrılmıştır. 6 haftalık deney boyunca kontrol grubu, D vitamini içeren standart yemle beslenen denekler, standart aydınlatma koşulları altında, UV-B yayan floresan aydınlatma altında, standart 12 saat aydınlık-12 saat karanlık döngüde tutulmuştur. D vitamini eksikliği modeli oluşturulan deney grubunda ise, denekler 6 hafta D vitamini içermeyen yemle beslenerek, vücutta D vitamini aktivasyonuna neden olan UV-B yaymayan ampüllerin kullanıldığı ortamda, standart 12 saat aydınlık-12 saat karanlık döngüde barındırılmıştır. Deney sonunda deneklerden alınan serum örneklerinde 25(OH)D düzeyleri HPLC yöntemiyle ölçülerek, 20 ng/mL ve altında olan deneklerde D vitamini eksikliği modelinin olduğu belirlenmiştir. Sonrasında kontrol ve D vitamini eksikliği gruplarındaki denekler çiftleşmenin tespit edilmesinden sonra gebeliğin ilk haftasında sakrifiye edilmiş, elde edilen ovaryum dokularının histolojik olarak incelenmesinde Hematoksilen-Eozin yöntemi kullanılmıştır. Histokimyasal incelemeler sonucunda kontrol gruplarında ovaryum dokusu ve ovaryum folliküllerinin normal histolojik yapılarında olduğu izlenmiştir. D vitamini eksikliği oluşturulan grupta, granüloza hücreleri ile teka yapılarının normal düzenlenimlerinin bozulduğu gözlenmiştir. Ayrıca gelişimlerinin farklı aşamalarında bulunan primordial, unilaminar ve multilaminar primer, sekonder, Graaf follikülleri, atretik folliküller ve korpus luteum yapıları ovaryum dokusundan alınan seri kesitlerde sayılmıştır. Sekonder ve Graaf folliküllerin D vitamini eksikliği grubunda kontrol grubuna kıyasla istatistiksel olarak anlamlı derecede az olduğu tespit edilmiştir. D vitamini eksikliğinin ovaryum dokusunda histokimyasal düzeyde folliküller hasara neden olduğu ve follikülogenezisin özellikle son basamaklarında matürasyonu bloke ederek olgun follikül gelişiminde azalmaya neden olduğu kanısına varılmıştır.

**Anahtar Kelimeler:** D vitamini eksikliği, Erken gebelik, Ovaryal folliküller, Histokimya

#### Özet

Flavonoidler, bitkilerde bulunan sarı, mavi ve kırmızı renkli pigmentlerin kaynağıdır. 2-fenil-benzo-a-piron yapısında bulunan meyvelerde, sebzelerde çay ve şarap gibi maddelerde bulunurlar. H ve OH gruplarının benzen ve heterosiklik yapılarına bağlanma şekilleri ile farklı isim alırlar. Antioksidan özellik göstermeleri flavonoidlerin en önemli biyolojik özelliklerinden biridir. Flavonoidler üzerinde yapılan araştırmalarda flavonoidlerin farklı türde kanser hücrelerine etki edip kanser oluşumunu azalttığı görülmüştür[1]. Kuarsetin bitkilerde, sebze ve meyvelerde fazlaca bulunan flavonoid çeşididir. Turpgiller, üzüm, elma, domates ve yaban mersini gibi besin kaynaklarında farklı miktarlarda yer alırlar. Soğan yüksek miktarda kuarsetin içeren bitkilerden biridir. Kuarsetinin insanda papiller tiroid gibi kanser hücrelerinde apoptotik hücre ölümünü harekete geçirdiği söylenmiştir. Kuarsetin ve kombonisyonlarıyla çalışmalar yapılmış olup antikanser madde şeklinde kullanılabilir yapılarının olduğu açıkça belirlenmiş, farklı olarak genotoksik ve toksik etki gösterebileceğini söyleyen araştırmalarda vardır[2]. Krizin (5,7-dihidroksiflavon) Passiflora gibi bitkilerden izole edilen flavonoid çeşididir. Doğal olan bu molekül antioksidan, anti-inflamatuar, anti-kanser, nöroprotektif ve anti-apoptotik gibi çeşitli etkiler gösteren farmakolojik özellik gösterir[3]. Flavonoidler endojen antioksidanların özelliklerini artırmanın yanı sıra doğrudan radikal süpürücü özellikleri oluşu ile reaktif oksijen türlerinin moleküler proteinlerdeki sülfidril bağları, çoklu doymamış yağ asitleri ve DNA'daki nükleotidler ile reaksiyona girerek doku hasarına neden olmalarını önlemektedirler. Çalışmalar neticesinde krizinin 5. ve 7. Konumlarındaki hidroksil grupları ile serbest radikalleri süpürücü özelliğe sahip olduğu bildirilmiştir[4]. Bu çalışmamızda ligant olarak kuarsetin ve krizin (Şekil 1) kullanılarak, yeni paladyum(II) kompleksleri sentezlendi. Komplekslerin yapıları element analizi, FT-IR, NMR, kütle, UV-GB, TGA-DTA yöntemleri ve manyetik duyarlılık ile iletkenlik ölçümleri ile karakterize edildi. Kuarsetin ve krizin ile yeni paladyum(II) komplekslerinin antioksidan özellikleri 2,2-difenil-1-pikrilhidrazil (DPPH) radikal süpürme yöntemi ile incelendi. DPPH radikalının stok çözeltisi DMSO ortamında 1 mM olarak hazırlandı ve 160 µM'a seyreltilti. Bileşiklerin stok çözeltisi DMSO ortamında 1mg/10 mL olarak hazırlandı.

Şekil 1. Kuarsetin (a) ve krizinin (b) açık yapıları

**Anahtar Kelimeler:** flavonoid, kuarsetin, krizin, antioksidan, kompleks, radikal süpürme.

#### Abstract

Hydrogen, which has a high gravimetric energy density, is a clean and sustainable energy carrier among alternative energy sources. Hydrogen can be produced cleanly by electrolysis of water. The electrolysis of water takes place through two half-reactions, the hydrogen evolution reaction (HER) at the cathode and the oxygen evolution reaction (OER) at the anode. Water is thus decomposed into oxygen and hydrogen. The hydrogen evolution reaction (HER) is an electrochemical process involving redox reactions at the electrode/electrolyte interface. One of the most important parameters for the industrial use of hydrogen production with HER is the development of active and economical electrocatalysis. In this study, the mesoporous carbon sample was prepared by the hard template method using the KIT-6 material prepared by the hydrothermal synthesis procedure. Ni-S and Fe-S active phases were synthesized by using the hydrothermal method. Wet impregnation was used for the preparation of the 10% by weight Ni-S@mezoC and Fe-S@mezoC catalysts. N<sub>2</sub> adsorption-desorption, XRD and SEM analyses were used to characterize the catalysts. Both the support material carbon and the catalysts exhibited Type-IV isotherm, which expresses mesoporosity. The surface area of the mesoporous carbon support was found as 1156 m<sup>2</sup>/g. Due to the loading of metal sulfides on the support, the surface area of the Ni-S@mezoC and Fe-S@mezoC catalysts decreased due to clogging of the pores. Amorphous carbon phase was detected in the XRD patterns of the mesoporous carbon support. The Ni-S catalyst mainly exhibited the NiS<sub>2</sub> crystalline phase, while the crystal structure of the Fe-S catalyst was found to be FeS<sub>2</sub>. Electrocatalytic activity of the mesoporous carbon and the catalysts were investigated in 0.5 M H<sub>2</sub>SO<sub>4</sub> electrolyte medium by using linear sweep voltammetry (LSV) test. The overpotential of the mesoporous carbon support was 433 mV. The most active catalyst was Ni-S which showed the lowest overpotential value as 232 mV.

**Keywords:** HER, mesoporous carbon, KIT-6, metal sulfide, catalyst

## Özet

Yaşamın birçok alanda kullanılan biyokimyasal bileşikler organizmaların hücrelerini ve diğer yapılarını oluşturmaktadır ve yaşam süreçlerini yürütmektedir. Proteinler, aminler, poliaminler, kompleks karbonhidratlar, organik asitler, lipitler, fenoller, flavonoidler, terpenoidler, aromatik bileşikler, hormonlar ve vitaminler gibi biyokimyasal bileşikler ve ikincil metabolitler, bitkilerinin fizyolojisi ve metabolizmasında çok önemli bir rol oynamaktadır. Hammadde olarak kullanılan doğal kaynaklı biyokimyasal bileşikler dünya üzerindeki birçok farklı bitki grubundan sağlanmıştır. Bu bitki gruplarından birisi de özellikleri bakımından birçok farklı alanda çok eski zamanlardan beri kullanılmakta olan karayosunlarıdır. Karayosunları çok uzun zamandan beri çeşitli hastalıkların tedavisinde kullanılmaktadır ve bu faydalarından dolayı son yıllarda yapılan çalışmalarda sıkça tercih edilmektedir. Bu çalışmada *Calliargonella cuspidata* (Hedw.) Loeske karayosunu türü etanol, metanol ve n-Hekzan olmak üzere üç farklı çözücüyle ekstrakte edilmiş ve Gaz kromatografisi ve kütle spektrometresi analizleri ile biyokimyasal içeriği belirlenmiştir. Elde edilen sonuçlar neticesinde, *C. cuspidata* karayosununun etanol ekstraktında 1-Allyl-4-(phenylthio)-6-(3-(trimethylsilyl)prop-2-ynyl)-5,6-dihydropyridin-2(1H)-one ve Phenol, 2,2'-methylenebis[6-(1,1-dimethylethyl)-4-(1-methylpropyl)-]; metanol ekstraktında Phytol ve Neophytadiene; n-Hekzan ekstraktında ise 4-((E)-3-phenylallylideneamino)-5-(4-isopropylthiazol-2-yl)-4H-1,2,4-triazole-3-thiol bileşiklerinin varlığı tespit edilmiştir.

**Anahtar Kelimeler:** *Calliargonella cuspidata*, karayosunu, GC/MS, biyokimyasal içerik

#### Abstract

Levodopa-induced dyskinesia (LID) is a challenging motor complication associated with the long-term use of levodopa, which has remained the gold standard treatment for over 50 years in Parkinson's disease. Ketamine, an N-methyl-D-aspartate (NMDA) receptor antagonist, is a widely available drug developed as a general anesthetic. In recent years, evidence has emerged suggesting the potential utility of ketamine in various neuropsychiatric illnesses. This pilot study explores the effect of ketamine treatment on LID, aiming to provide insights into its therapeutic potential. Male Sprague-Dawley rats were unilaterally lesioned with 6-hydroxydopamine to induce the hemi-parkinsonism model and received levodopa + benserazide (12 mg/kg/day, 15 mg/kg) treatment for seven days. Dyskinesia was quantified using the Abnormal Involuntary Movements (AIMs) scores, and the rats developed stable dyskinetic movements subjected to ketamine treatment (5 x i.p. injections two hours apart). The AIMs scores were assessed before and after ketamine treatment. Our findings reveal a notable reduction in AIMs scores following ketamine treatment, underscoring the therapeutic potential of ketamine in managing LID. Notably, the Mann-Whitney U test demonstrated a statistically significant decrease in AIMs scores ( $U=0$ ,  $p=0.05$ ). This study provides preliminary evidence of the potential of ketamine to reduce AIMs scores in levodopa-induced dyskinesia. Although these findings are promising, further research in larger cohorts and in-depth exploration of the underlying mechanisms are needed. This pilot study lays the foundation for our further comprehensive research into the mechanisms of ketamine's effect on dyskinesia.

**Keywords:** Dyskinesia, Ketamine, AIM, Parkinson

\*Sorumlu yazar e-mail: s.muhcu2021@gtu.edu.tr

#### Özet

Kontrollü salım teknolojisi, farmasötik ve tıbbi uygulamalarda büyük bir potansiyele sahiptir ve sağlık alanındaki etkisi nedeniyle hem akademi hem de endüstride yoğun bir araştırma faaliyeti konusudur. Teknoloji, tedavinin yüksek etkinliğini sağlar, tedavi maliyetini düşürür, toksisite risklerini ve ilacın yan etkilerini azaltır, ilaçların kanda ve plazmada kararlı emilim seviyeleri ve daha fazla hasta konforu sağlar. Ayrıca uyarılara yanıt veren ilaç taşıyıcı sistemler, ilaçların belirli yerlerde ve zamanlarda kesin miktarlarda kontrollü olarak verilmesi potansiyeline sahip oldukları ve bu nedenle her kişinin ihtiyaçlarına göre uyarlanabildikleri için bu tür durumların tedavisi için daha fazla dikkat çekmiştir. Işık, pH, sıcaklık, elektrik, enzimler ve manyetik alanlar gibi halen araştırılmakta olan çeşitli dış uyaran türleri vardır. Ayrıca, bu tür cihazlar vücudun dışından tetiklenebilmektedirler. Her uyaran türünün kendine göre avantajları vardır, bu avantajların yanı sıra elektriksel uyarım kullanımının ON-OFF salım avantajları vardır, akımın büyüklüğü hassas bir şekilde kontrol edilebilir, bu şekilde salınan ilaç miktarı da kontrol edilir. İletken polimerler (CP'ler), yarı iletkenlere/metallere yakın elektriksel özellikler ve ek olarak elektrokimyasal ve optik özellikler kazandıran genişletilmiş  $\pi$ -bağlı bir polimer ailesidir. Bu benzersiz özellikler, onları çeşitli teknik endüstrilerde popüler hale getirdi.

Kontrollü salım teknolojisi birçok avantaj sağladığından, kontrollü ilaç salımını sağlayabilen biyoyumlu malzemelere yönelik bir pazar ihtiyacı vardır.

Bu çalışmada, yeni CP'ler hazırlanmış ve çeşitli tekniklerle (FTIR, TGA, CV) karakterize edilmiştir. Daha sonra, hazırlanan bu yeni CP'ler arasında en iyi iletkenlik ve mekanik özellik gösteren CP'nin elektrikle tetiklenen ilaç salım profili incelenmiştir.

**Anahtar Kelimeler:** Elektroaktif hidrojel, kontrollü ilaç salım sistemleri, elektriksel uyarımla ilaç salımı

#### Özet

Gıda israfı, dünya genelinde ciddi bir sorun olup sürdürülebilir gıda üretimi ve tüketimi için büyük bir engel teşkil etmektedir. Bu israf sadece gıda kıtlığına değil, aynı zamanda çevresel etkilere de yol açmaktadır. Özellikle sınırlı gıda kaynaklarına sahip bölgelerde gıda mevcudiyetini sınırlar ve küresel olarak su ve toprak kullanımını, gereksiz sera gazı salınımını ve verimsizliği içeren olumsuz çevresel etkilere neden olur. Özellikle artan kentsel nüfus, taze, sağlıklı, pratik ve hızlı gıda talebini artırmaktadır. Ancak bu talep, gıda kaybını ve israfını da artırmaktadır. Akıllı ambalaj, gıda kaybını ve israfını azaltmada önemli bir rol oynayabilir, çünkü gıda kalitesini koruyarak ve gıda güvenliğini sağlayarak etkili bir şekilde kullanılabilir. Gıda güvenliğini izlemek amacıyla çeşitli gıda sensörleri geliştirilmektedir. Akıllı ambalajlarda kullanılan bu sensörler, gıda kalitesi, menşei, kontaminasyon derecesi gibi bilgileri algılayabilir ve iletebilir. Bu sensörler aracılığıyla gıdadaki kimyasal, biyokimyasal, fiziksel ve mikrobiyolojik değişiklikler izlenebilir. Örneğin, tazelik sensörleri olan pH indikatörleri, gıdanın bozulma sürecini izlemek için kullanılabilir. Bozunma sonrasında ortaya çıkan biyojenik amin gazları, pH seviyesini değiştirir ve bu değişiklikler kolorimetrik veya florojenik indikatörlerle izlenebilir. Bu şekilde, tüketiciye gıdanın bozulma süreci hakkında bilgi verilebilir. Bu amaçla, gıda kaybını önlemek için kumarin temelli yeni bir tazelik sensörü geliştirmiştir. Bu bileşiğin fotofiziksel özellikleri çeşitli çözücülerde belirlenmiştir. Daha sonra bu bileşiğin gıda bozunmaları sonrasında ortaya çıkan amonyak ile etkileşimi çalışılmıştır. Hem çözücü ortamında hem de katı destek üzerinde sensörün etkisi incelenmiştir. Bu çalışmanın sonuçları, gıda kaybını ve israfını azaltmada akıllı ambalajların potansiyelini vurgulayabilir ve gelecekte daha sürdürülebilir bir gıda sistemi oluşturmak için önemli bir adım olabilir.

**Anahtar Kelimeler:** Kumarin, gıda israfı, akıllı ambalaj, biyojenik amin, sensör

### Özet

İnsanlık tarihinin başlangıcından bu günlere dek bitkiler, gıda, ilaç, inşaat, tekstil ve enerji gibi çeşitli sektörlerde kullanılmış ve kullanılmaya devam etmektedir. Özellikle ilaç sektöründe, bitkiler en az diğer sektörlerde oldukları kadar önemli olup ilaç arayışlarında ilk başvurulan kaynaklardan olmuşlardır. Bu kaynak bitki gruplarından birisi de karayosunlarıdır. Potansiyel olarak içerdikleri değerli bileşenler sayesinde ilaç araştırmalarında önemli roller üstlenmektedirler. Fakat karayosunlarının içerdikleri önemli bileşenlerin keşfi ve izolasyonu diğer bitkilere nazaran daha komplike olabilmektedir ve bu bileşenlerin düşük konsantrasyonlarda bulunabilme ihtimalleri kullanımlarını kısıtlamaktadır. Bu sebeple karayosunlarının potansiyel olarak içerdikleri bileşenlerin biyokimyasal analizlerinin yapılması önemlidir. *Homalothecium philippeanum*, Brachytheciaceae familyasına üye olan bir karayosunu olup ormanlar, sulak alanlar ve kayalıklar gibi çeşitli habitatlarda yaşayabilmeleri ile bilinmektedirler. Kuzey Yarımküre'nin ılıman bölgelerinde ve yüksek rakımındaki dağlık bölgelerinde yaygın olarak bulunmaktadırlar. Gerçekleştirilen bu çalışmada *H. philippeanum*'un biyokimyasal içerik analizi için farklı çözücüler kullanılmıştır. Etanol, metanol ve n-hekzan çözücülerinde gerekli ekstraksiyon işlemleri yapıldıktan sonra gaz kromatografisi ve kütle spektrometresi cihazı ile *H. philippeanum*'un içerik analizi yapılmıştır. Yapılan analiz sonucunda *H. philippeanum*'un etanol ve metanol ekstraktlarında 1,2-Benzendikarboksilik asit, bis(2-metilpropil) ester, 2,2,4-Trimetil-1,3-pentandiol diizobütrat ve Propanoik asit, 2-metil-, 3-hidroksi-2,2,4-trimetilpentil ester bileşikleri; n-hekzan ekstraktında ise 2,6-Dibromo-3,5-difloro-4-piperidinilpiridin ve Oktasiloksan, 1,1,3,3,5,5,7,7,9,9, 11,11,13,13,15,15-hekzadekametil- bileşikleri başlıca bileşen olarak tanımlanmıştır.

**Anahtar Kelimeler:** Karayosunu, *Homalothecium philippeanum*, Biyokimyasal içerik, GC-MS

#### Abstract

Adult stem cells, including mesenchymal stromal cells (MSCs), are easily isolated from various human tissues like adipose tissue and bone marrow. MSCs possess immunomodulatory abilities that affect numerous immune cell types and can differentiate into mesenchymal tissues such as bone, cartilage, and fat cells. They are predominantly well-tolerated and non-tumorigenic and have shown potential benefits in remedying various disorders. This has positioned MSCs as a promising source of stem cells for clinical applications. As of August 2023, there were over 1362 registered clinical trials, exploring their potential in treating conditions such as diabetes, cancer, cardiovascular diseases, and musculoskeletal disorders. MSCs were conventionally cultured and differentiated on flat two-dimensional (2D) surfaces composed of glass or polystyrene, which could cause abnormal cell polarity, chromosomal changes, reduced cell viability, and an altered differentiation potential. To overcome these issues, three-dimensional (3D) scaffolds have been engineered to mimic the natural MSC microenvironment, offering a more expansive culture surface. Recent research indicates that the therapeutic efficacy of MSCs, as observed in proof-of-concept and clinical studies, is not solely attributed to their integration into tissues but is remarkably influenced by the characteristics of 3D-scaffolds. However, visualizing cells within 3D frequently encounters obstacles, such as low signal-to-noise ratios, primarily due to the light-absorbing properties of hydrogels. In this study, adipose tissue-derived MSCs were cultured within a novel hydrogel that are comprised of plant-derived nanofibrillar cellulose. This 3D hydrogel formed nanofibers, consisting of a porous network suitable for MSC. Significantly, it exhibited minimal light absorption in the visible spectrum and displayed biocompatibility with MSCs, ensuring their viability. Moreover, the hydrogel facilitated uncomplicated light-based imaging techniques, including the utilization of conventional dyes and immunocytochemistry within 3D context. To conclude, this innovative 3D hydrogel holds promise as a material for expanding MSCs and studying cellular morphology and behavior within 3D environment.

#### Abstract

Bu çalışmanın amacı ilaca dirençli epilepsisi olan çocuklarda besin alımı ile yaşam kalitesi ve nöbet sayısı arasındaki ilişkiyi değerlendirmektir. Bu çalışma, İzmir Tepecik Eğitim ve Araştırma Hastanesi Çocuk Nöroloji polikliniğinde takip edilen 2–18 yaş arası ilaca dirençli epilepsisi tanısı olan hastalarla yürütülmüştür. Çalışma verileri yüz yüze görüşme yöntemiyle anket kullanılarak elde edilmiştir. Besin alımının değerlendirilmesi için katılımcılardan üç günlük besin tüketim kaydı alınmıştır. Yaşam kalitesini değerlendirmek için çocuklar için yaşam kalitesi ölçeği (PedsQL) kullanılmıştır. Ölçekte yaşam kalitesi; fiziksel sağlık, duygusal işlevsellik, sosyal işlevsellik ve okul işlevselliği olmak üzere dört alanda puanlandırılmıştır. Katılımcıların %52,8'i kız olup tüm katılımcıların yaş ortalaması 10,6±4,85 yıl'dır. Haftalık nöbet sayısı ortalama 15,2±27,42 olarak belirlenmiştir. Toplam enerji alımları 1210,2±390,75 kkal idi. Toplam enerjinin %46,7 karbonhidrat, %16,2'si protein ve %37'si yağlardan sağlanmaktaydı. PedsQL 'ye göre katılımcıların ortalama fiziksel sağlık puanı 72,4±31,16 puan, duygusal sağlık puanı 71,5±20,39, sosyal işlevsellik puanı 80,0±30,76, ve okul işlevselliği puanı 57,6±25,39 olarak tespit edildi. Yaşam kalitesi ölçek puanları her iki cinsiyette benzer dağılım göstermekteydi (p>0,05). Okul işlevselliği ile diyet yağ yüzdesi (r=-0,492, p=0,001) arasında negatif yönlü, karbonhidrat yüzdesi ile (r=0,523, p<0,001) pozitif yönlü anlamlı ilişki saptanmıştır. Sosyal işlevsellik ile diyet yağ yüzdesi (r=-0,349, p=0,010) arasında negatif yönlü diyet karbonhidrat yüzdesi (r=0,391, p=0,004) ile pozitif yönlü ilişki saptanmıştır. Haftalık nöbet sayısı ile duygusal işlevsellik (r=-0,600, p=<0,001) negatif yönlü ilişki iken enerji alımı (r= 0,312, p=0,023) ile pozitif yönlü ilişkili bulunmuştur. Bu çalışmada ilaca dirençli çocuklarda besin alımı ile yaşam kalitesi ve nöbet sayısı arasında ilişki olduğu belirlenmiştir. Bu çocuklarda nöbet sayısını kontrol altına almak ve yaşam kalitesi artırmaya yönelik bireysel beslenme müdahaleleri geliştirilmelidir.

**Keywords:** ilaca dirençli epilepsi, epileptik nöbet, besin alımı, yaşam kalitesi.

#### Abstract

Flexible strain sensors have gained widespread popularity due to their diverse applications in wearable technology, health monitoring, and biomedical devices. Capacitive sensors are an important type of strain sensors. Their sensitivity, or gauge factor, closely tied to dielectric properties. One effective method to boost sensitivity is the incorporation of high dielectric constant materials with polymer base without decreasing elasticity. In this study, we present a practical silicon-based sensor enriched with barium titanate as an additive. The resulting sensor is being tested; significant improvements are obtained. Dielectric constant and gauge factor increased by almost 35% and the elasticity decreased by approximately by 15%. Barium titanate can be used to improve polymer based flexible strain sensors sensitivity.

**Keywords:** Flexible strain sensors, gauge factor, barium titanate, wearable sensors

<sup>2</sup>Bursa Uludağ Üniversitesi, Fen-Edebiyat Fakültesi, Kimya Bölümü, Bursa

berannoner@gmail.com.tr

#### Özet

Bu çalışmada, adli bir vakada olay yerinde bulunan şüpheli veya şüphelilerden ele geçirilen ipliklerdeki lif yapılarının SEM (Taramalı Elektron Mikroskopisi) ve FTIR (Fourier Dönüşümlü Kızılötesi Spektroskopisi) kullanılarak mukayese yoluyla aydınlatılması amaçlanmaktadır. Çalışmada maktulün boynundan elde edilen ip ve olay yerinden elde edilen ip lifleri öncelikle fiziksel yöntem incelenmesine tabii tutulmuştur. Ardından bu liflerin mukayesesi SEM (Cihaz marka modeli) ve FTIR (Cihaz marka modeli) cihazlarından elde edilen sonuçlar ile gerçekleştirilmiştir. Farklı materyaller üzerinden elde edilmiş iki adet lif numunesine ait FTIR spektrumlarının birbirine benzer olup örtüştüğü gözlemlenmiştir. SEM görüntülerinde aynı büyütme oranlarında oluşan şekiller ve aynı hızlandırma voltajında meydana gelen görüntülere bakıldığında bu iki lif numunesinin benzer oldukları tespit edilmiştir. Bu çalışmanın sonucunda olay yerinden elde edilen lif numuneleri ile şüpheli veya şüphelilerden elde edilen lif numuneleri FTIR spektrumları ve SEM görüntülerinden söz konusu numunelerin fiziksel ve kimyasal olarak benzerlik gösterdiği görülmüştür. Bu bulgulardan yola çıkarak olay yerinden elde bulunan ve şüphelilerden elde edilen liflerin kaynağının aynı materyal olabileceği belirlenmiştir.

**Anahtar Kelimeler:** Lif Analizi, Taramalı Elektron Mikroskopisi (SEM), FTIR (Fourier Dönüşümlü Kızılötesi) Spektroskopisi

### Inherently Antibacterial Polymeric Micelles for Antibacterial Agent Delivery

Hanan Paşaoğlu Belal, Serap Derman, Murat Topuzoğulları

Yıldız Technical University, Department of Bioengineering, Istanbul, Turkey.

hananvic95@gmail.com

#### Abstract

One of the major problems that threatens the healthcare system worldwide is the multidrug- resistance of pathogenic bacteria against antibiotics. The advanced resistance of bacteria towards conventional antibiotics stimulates rapid intervention to find a new solution against this serious problem that can lead to several diseases and infections in human. Antibacterial polymers have been chosen as a promising alternative to traditional antibiotics, due to their unique mechanism action against bacteria, since antibacterial polymers having cationic amphiphilic structure show selectivity to bacteria via electrostatic interactions between the positive charges on the polymer and the negative charges on the surface of the bacterial cell membrane.

In this study antibacterial polymeric micelles carrying Juglone as antibacterial drug were produced using cationic co-polymers of 4-vinylpyridine (4VP) and oligo (ethylene glycol) methyl ether methacrylate (OEGMA) to obtain inherently antibacterial polymeric micelles as drug delivery system.

The produced copolymers were characterized by NMR, FT-IR, DLS spectroscopies and GPC. The hydrodynamic diameter of produced cationic micelles loaded with different Juglone concentrations ranged between 131-167 nm and the polydispersity indices were below 0.3.

**Keywords:** antibacterial cationic polymer, micelle, Juglone.

**Acknowledgements:** This study was supported by Yıldız Technical University Scientific Research Projects Coordination Unit [Project No: FCD-2022-4900].

#### Abstract

This study aimed to produce an anti-ulcer food supplement based on the brown seaweed "Cystoseira sensu lato", algae that has never been used as a food supplement. Our project is an innovative idea that falls within Decree 1275. A physicochemical study of the aqueous, methanolic and ethanolic extract and an in vivo study on wistar rats were carried out to determine the lethal dose (LD50), the effective dose (ED50) and to study the anti-ulcer activity of this algae. The data obtained showed a zero degree of toxicity with an LD50 equal to 10,000 mg/kg. A strong anti-ulcer effect was noted for the three extracts (aqueous, ethanolic and methanolic) as well as for C. sensu lato algal powder. The different doses of seaweed (50, 100 and 150 mg/kg) significantly reduced the percentage of ulceration with a high percentage of inhibition. It was found that the brown alga powder 'Cystoseira sensu lato' at 150 mg/kg gave a maximum effect in reducing gastric ulceration. By following the dose-effect curve, we can estimate the ED50 of the brown alga 'Cystoseira sensu lato' at between 25 and 75 mg/kg. Our results also show that the brown alga C.sensu lato is rich in polyphenols and flavonoids and has significant antioxidant properties. It would therefore be interesting to carry out further studies to confirm and analyse other therapeutic activities of this miraculous algae

**Keywords:** Cystoseira sensu lato, Anti-ulcer food supplement, Wistar rats , LD50 , ED50

#### Abstract

Polycystic ovary syndrome (PCOS) is the most common gynecological endocrinopathy in women of reproductive age . This study aims to estimate the prevalence of PCOS among female students at Tlemcen University-Algeria and to determine their nutritional profile. A prospective, cross-sectional study was conducted at the University of Tlemcen. 1124 female students aged  $21.67 \pm 3.21$  years were recruited. Cases of PCOS were identified according to the Rotterdam criteria through a clinical interview, anthropometric measurements and an assessment of the participants' eating habits in the different faculties of the university. The data was analysed using Graph pad prism 9 software. The results of this study show that polycystic ovary syndrome affects around 12.81% of female students at the University of Tlemcen. The highest percentages were found in the faculties of natural and life sciences, earth and universe (25.34%), literature and languages (19.86%) and medicine (15.02%). Most subjects with PCOS are overweight (43.83%). It was also noted that most subjects with PCOS have irregular cycles and signs of hyperandrogenism. We also found that a large percentage of the PCOS population prefers fried foods (45%) and sweets (34.2%). Moreover, we noted that only 26% of PCOS patients engage in regular physical activity. The results revealed that the prevalence rate of PCOS is high among female students at the University of Tlemcen , Algeria. It is important for women to be aware of their lifestyle and nutritional profile in order to prevent this and other diseases.

#### Abstract

Alkaloids belonging to the Amaryllidaceae family are known for their antiviral and antitumor properties, with significant components such as galantamine widely used in the treatment of Alzheimer's disease. Additionally, an alkaloid named lycorine exhibits potent antiviral effects against poliovirus, measles, and Herpes simplex type 1 viruses. One of the important sources for the commercial production of galantamine is the *Leucojum aestivum* L. plant. *L. aestivum* is the sole native species of the *Leucojum* genus in Turkey and belongs to the Amaryllidaceae family. This plant thrives in damp and semi-shaded areas, ranging from sea level to high altitudes, and is locally known by names like 'yaz kar tanesi' (summer snowflake), 'loddon zambağı,' and 'kar tanesi zambağı' (snowflake lily). However, the collection of these plants from the wild is limited and poses a threat to their existence. Therefore, understanding the chemical composition of the seeds of this plant is of great importance. In this context, it has been determined that the seed husks of *L. aestivum* exhibit high DPPH free radical activity (IC<sub>50</sub>: 214.97 mg/ml) and also possess important characteristics such as total flavonol content, total flavonoid content, total phenolic content, total proanthocyanidin content, and total tannin content.

**Keywords:** Antioxidant activity, *Leucojum aestivum*, Seed coat

#### Abstract

The loss of moisture during storage of fresh carrot can be predicted by developing a simultaneous heat and mass transfer model to predict the movement of water through diffusion, evaporation and convection and it can then be used to predict water loss at different storage conditions. Understanding the relationship between temperature and relative humidity is useful to minimize the water loss and to prolong the shelf life of vegetables. In this study a 3-dimension simultaneous heat and mass transfer mechanistic model was developed based on two primary mechanisms: heat transfer during the cooling of carrots and mass transfer due to evaporation of moisture from the carrots. The developed model was solved using the commercial software COMSOL Multiphysics. The simulated model was validated with experimental data at the storage conditions 8°C - 95% relative humidity (RH), 8°C - 60% RH and 30°C - 82% RH for the moisture profile and 8°C-80% RH for the temperature profile, respectively. The model was found to fit the experimental data well with a determination coefficient (R<sup>2</sup>) ranging from 0.80 to 0.99. The concentration of water inside carrot reduced from 51223 mol/m<sup>3</sup> to 15205 mol/m<sup>3</sup> when stored at 8°C - 60% RH for 240 hour and at 30°C - 82% RH the concentration of water decreased from 50130 mol/m<sup>3</sup> to 28285 mol/m<sup>3</sup>. This indicates that relative humidity has a greater impact on moisture loss than temperature at the storage condition. The model predicted that the carrot has to be stored at higher than 90% RH and at temperature lower 5°C in order to maintain the water loss of lower than 8% for 240 day storage.

## POSTER PRESENTATION

### QSPR models for predicting the soil sorption partition coefficient (Koc) using machine learning algorithms

S. Batouche

University Mohamed Cherif Messaadia, Faculty of Science and Technology, Department des Sciences de la Matière Souk Ahras , Algeria  
Laboratoire des Sciences et Tehniques de l'eau et environnement

#### Abstract

A comparative study was undertaken to test the ability of different machine learning algorithms to predict the soil sorption partition coefficient (Koc) for organic compounds. In this work, three different quantitative structure-property relationship (QSPR) models were developed using four molecular descriptors. To develop the QSPR models, three different machine learning algorithms were applied and compared: random forest (RF), support vector machine (SVM), and deep neural network (DNN) algorithms. Based on the statistical parameters, the results showed that the DNN-QSPR model outperformed the RF-QSPR and SVR-QSPR models in terms of accuracy and prediction, ( $R^2 = 81,4\%$  mae = 0,3834, mse = 0,0604)

**Keywords:** QSPR-artificial intelligence,-machine learning, random forest-support vector machine-soil sorption coefficient.

#### Özet

Ankara çayı, Türkiye'nin en büyük nehirlerinden birisi olan Sakarya Nehri'nin önemli bir kolu olmakla birlikte, yüksek kirlilik baskısı altında bulunan bölgenin kirlilik yükünü tüm havzaya taşıması sebebiyle izlenmesi ve takip edilmesi gereken önemli bir su kaynağıdır. Son yıllarda artan nüfus, kentleşme ve sanayileşmeyle birlikte, su tüketiminin kontrolsüz bir şekilde artması ve tarımsal faaliyetlerde bilinçsizce kullanılan gübre ve tarım ilaçlarının su kaynaklarına karışması sonucunda su kaynaklarındaki su kalitesinin izlenmesi oldukça önem kazanmıştır. Su kalite indeksi metodu ile su kalitesinin anlaşılması ve değerlendirilmesi oldukça pratik bir hal almıştır. Dünyada en çok kullanılan ve diğer su kalite indeks metodlarının dayanağını oluşturan su kalite indeksi Ulusal Sanitasyon Vakfı Su Kalitesi İndeksi (NSFWQI)'dir.

Bu çalışmada, Ankara Çayı'nda ilk kez kullanılan su kalite indeksi metodu çalışılmış ve su kalite indeksine bağlı su kalite sınıflarının tespit edilmesi hedeflenmiştir. Bu amaçla, Ankara Çayı'nın kaynağından başlayarak Sakarya Nehri ile birleştiği yere kadar akarsu boyunca seçilen on adet örnekleme istasyonundan 2019-2020 yıllarında mevsimsel olarak su örnekleri alınmıştır. Alınan numunelerde sıcaklık, pH, bulanıklık, fekal koliform, çözülmüş oksijen, derişimi ve doygunluğu, biyokimyasal oksijen ihtiyacı, toplam fosfat ve toplam nitrat analizleri yapılmış ve NSFWQI'ne göre su kalite sınıfları belirlenmiştir.

**Anahtar Sözcükler:** Su Kalite İndeksi, Ankara Çayı, NFS-WQI, Çubuk Çayı.

#### Abstract

While Ankara Stream is an important tributary of Sakarya River, one of the largest rivers in Turkey, it is an important water source that should be monitored and scrutinized since it carries the pollution load of the region that is under high pollution pressure to the entire basin. As a result of the uncontrolled increase in water consumption resulting from increasing population, urbanization and industrialization in recent years, and the careless uses of fertilizers and pesticides in agricultural activities that mix up with water resources, it has become very vital to monitor the water quality of water resources. The water quality index method has become very practical to understand and evaluate water quality. Specifically, the National Sanitation Foundation Water Quality Index, the basis of other water quality index methods, is the most widely used water quality index in the world.

In this study, the water quality index method, is used for the first time in Ankara Stream, with the aim of determining the water quality classification. For this purpose, in each season of 2019 and 2020, water samples were taken from ten sampling stations selected along the stream, starting from the source of the Ankara Stream to the point where it joins the Sakarya River. To be used in water quality index calculations, including taken sample's temperature, pH levels, turbidity values, fecal coliform, dissolved oxygen, concentration and saturation, biochemical oxygen demand, total phosphate and total nitrate analyzes, have been analyzed, and, consequently, Water quality classes are determined according to National Sanitation Foundation Water Quality Index.

**Keywords:** Water Quality Index, Ankara Stream, NSF-WQI, Sakarya River.

## GİRİŞ

Sürdürülebilir kalkınmanın hayat bulmasındaki en önemli unsurlardan bir tanesi “su”dur; suyun yokluğunda kalkınma olmaz, kalkınma olmazsa hayal edilen refahı yüksek seviyelere ulaşılamaz ve yoksulluk engellenemez (Turan ve Eren, 2008). Tarih seyirinde uygarlıkların medeniyete doğru adımlarını hızlandıran en önemli neden su kaynakları olduğu gibi yaşadığımız zaman diliminde de en önemli stratejik unsurlar arasında yer almaktadır.

Dünyanın artan nüfusu ve büyüyen ekonomi hem dünyanın ekolojik dengesini bozmuş hem de su kaynaklarını tehdit edecek seviyeye gelmiştir. Sınırlı kaynaklarla sınırsız büyüme hırsına kapılan üretim sistemi, doğal kaynaklar üzerinde aşırı baskı oluşturmakta ve bunun neticesinde küresel ısınma, iklim değişikliği gibi tamiri mümkün olmayan arızalara sebebiyet vermektedir (Kılıç, 2008).

Su kalitesi, insan faaliyetlerinin neden olduğu genel kirlilik nedeniyle tüm dünyada büyük bir sorun haline gelmiştir. Su kalitesi indeksleri, su kalitesini değerlendirmek, su kirliliğini kontrol etmek, su kalitesini eski haline getirmek veya iyileştirmek ve havzadaki en iyi yönetim uygulamalarının etkilerini değerlendirmek için kolay bir sistemdir (Quilbe vd., 2006). Su kalitesi indeksi, sucul ekosistemdeki genel su kalitesi koşullarını yansıtmaktadır. Bu nedenle su kalitesi indeksi, sulak alanların kalitesi ve olası kullanımları konusunda yöneticiler ve karar vericiler için basit ve anlaşılır bir uygulama olmuştur (Bordalo vd., 2001; Maraşlıoğlu vd., 2018).

Su kalitesini değerlendirmek için birçok farklı yöntem kullanılmakla birlikte, en fazla kullanılan geleneksel yöntemlerde, analizleri yapılan parametrelerin standart sınır değerlerle karşılaştırılması yapılarak su kalitesi ortaya konulmaktadır. Ancak, geleneksel yöntemlerle su kalitesi parametrelerini incelemek hem zaman ve maliyet açısından dezavantajlıdır, hem de analizler sırasında çevre kirliliği oluşturduğu için olumsuz etkilere sahiptir (Noori vd., 2019).

Zaman, maliyet ve çevre kısıtlamaları nedeni ile geleneksel yöntemlerin yerini su kalite indeksi modeli almaktadır. Az sayıda su kalitesi parametreleri kullanılarak, belirli bir zamanda, bir su kütlesine ait genel su kalitesi durumunun, tek bir değer olarak ifade edilmesini sağlayan su kalite indeksinin amacı, farklı birimlere sahip farklı parametreleri içeren anlaşılması zor su kalitesi verilerinin, daha anlaşılabilir hale gelmesini sağlayarak, su kalitesi konusunda uzman olmayan bireylerin veya kurum yöneticilerinin, su kalitesinin durumu hakkında bilgi edinmesini ve bu bilgileri anlaşılır, rahat ve hızlı bir şekilde kullanabilmesini sağlamaktır (Kaçan, 2020).

Su kalitesini etkileyen parametrelerin her birinin, kullanılabilir su tüketimi için kabul edilen su kalitesi üzerindeki etkisini sağlayan derecelendirme tekniği, su kalite indeksi olarak tanımlanmakta olup, yüzeysel sularda olduğu gibi yeraltı sularının kalitesini belirlemek ve içme suyu olarak kullanımının uygunluğunu tespit etmek için önemli bir ölçüdür (Varol ve Şekerci, 2018).

Su kalite indekslerinin kullanılması, su kalitesindeki zaman ve mekandaki değişikliklerin incelenmesine izin veren su kütlelerindeki su kalitesi durumunu değerlendirmek için basit ve güçlü bir araçtır (Noori vd., 2019).

Dünyada pek çok su kalite indeksi formları mevcuttur ancak en çok bilinen su kalite indeksleri; Kanada Su Kalitesi İndeksi (CWQI), British Columbia İndeksi (BCWQI), Oregon Su Kalitesi İndeksi (OWQI), Ulusal Sanitasyon Vakfı Su Kalite İndeksi (NSF WQI)'dir. Bu çalışmada Ankara çayının su kalite indeksi Ulusal Sanitasyon Vakfı Su Kalite İndeksi (NSF WQI) ile değerlendirilmiştir.

Bu çalışmada, Ankara Çayı'nın kaynağına yakın noktadan başlayarak Sakarya Nehri ile birleştiği yere kadar tespit edilen 10 istasyondan, 2019 yılında mevsimsel olarak su numuneleri alınmış, su kalite parametreleri ölçülerek NSF-WQI su kalite indeksi hesaplanmıştır.

## BULGULAR

Çalışmamız sonucunda elde edilen sıcaklık, pH, çözülmüş oksijen, nitrat, fosfat, BOİ, bulanıklık ve fekal koliform verilerinin mevsimsel değişimi Şekil 1’de verilmiştir. Elde edilen veriler Yerüstü Su Kalitesi Yönetmeliğine göre değerlendirildiğinde; sıcaklık, pH ve nitrat parametrelerinin I. sınıf, çözülmüş oksijen ve BOİ parametrelerinin III. sınıf ve fosfat değerlerinin ise IV. sınıf su kalitesinde olduğu tespit edilmiştir.

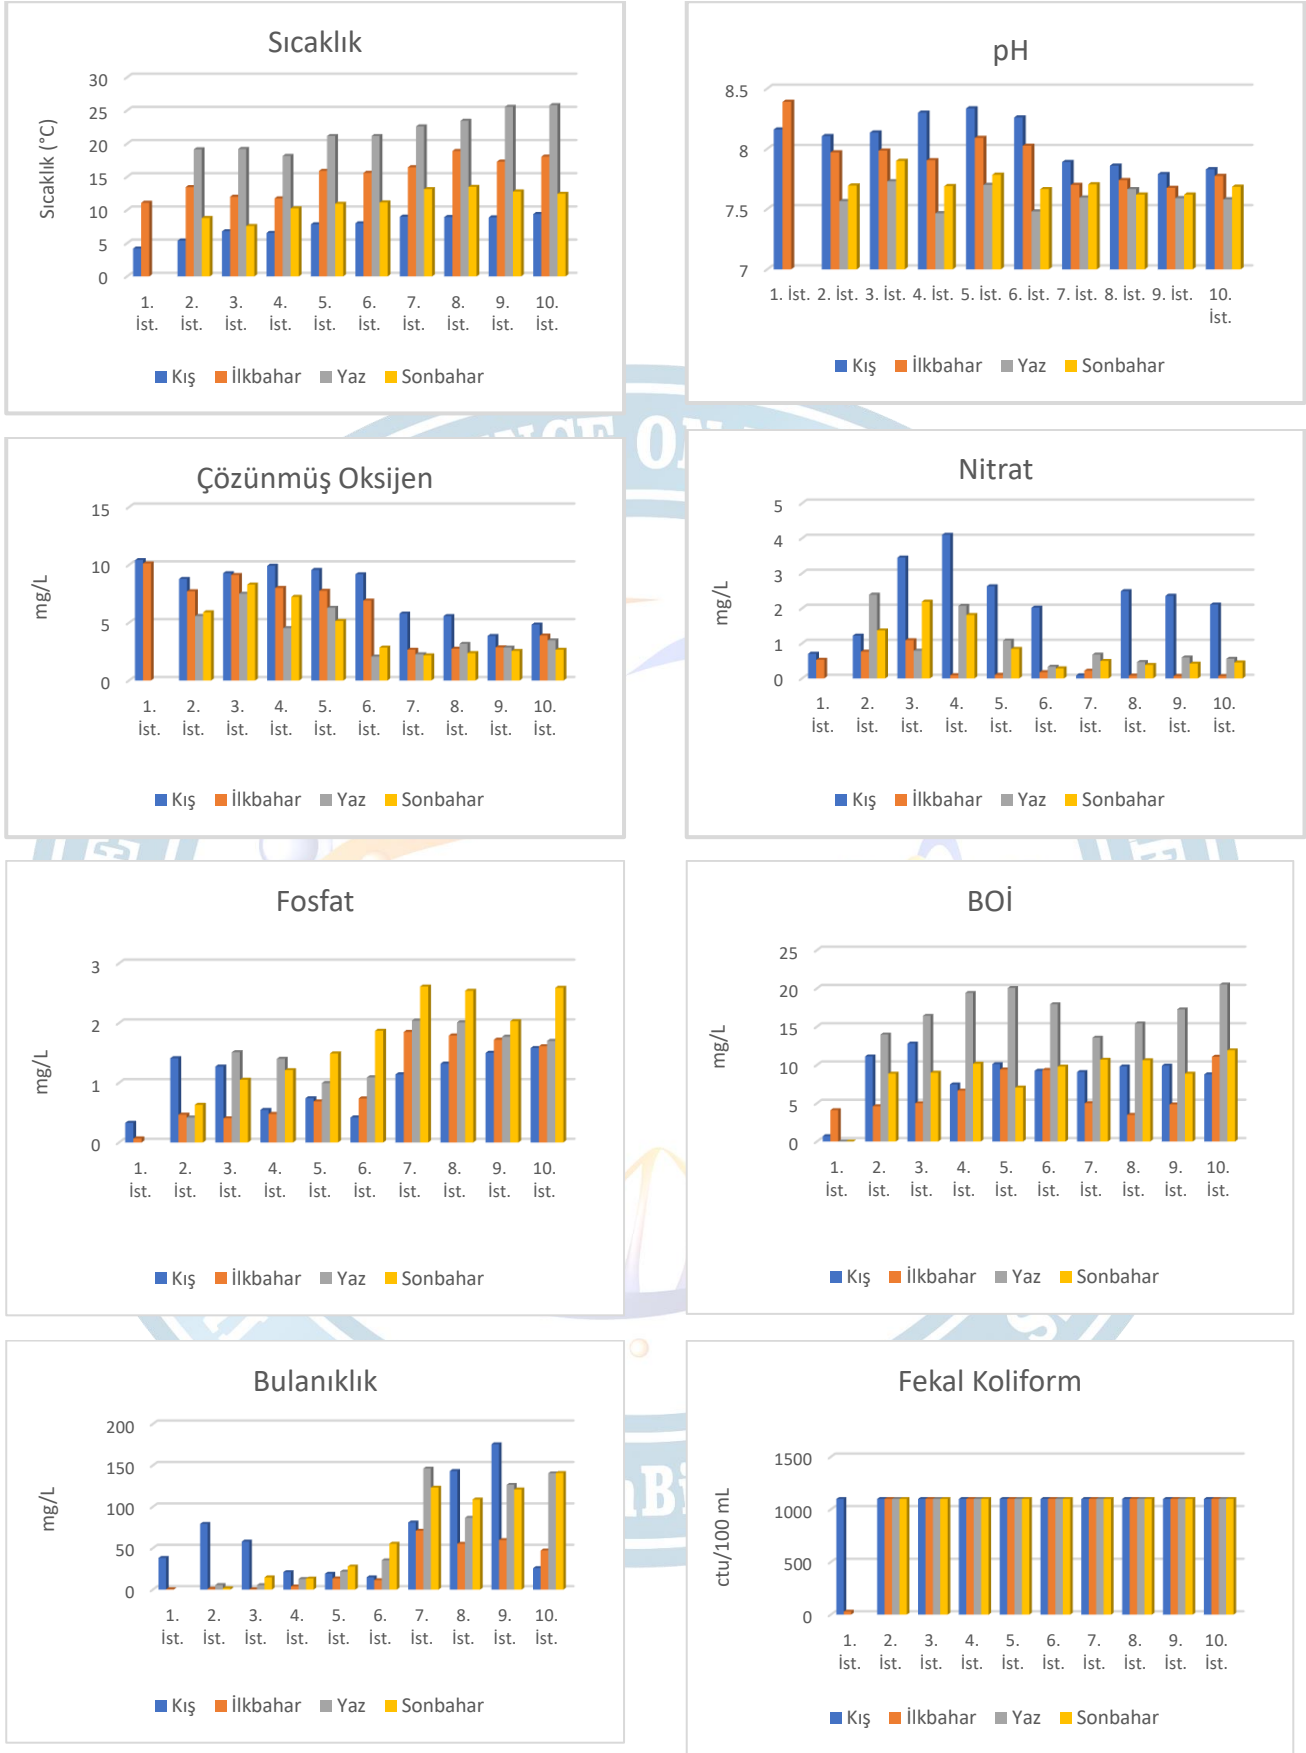

## TARTIŞMA VE SONUÇ

Sucul sistemlerde su sıcaklığı birçok fiziksel, kimyasal ve biyolojik olayı etkilediğinden dolayı önemli bir faktördür (Çiçek vd., 2017). Ankara Çayı’nda en yüksek sıcaklık yaz mevsiminde 25,3°C olarak 9. ve 10. istasyonlarda, en düşük sıcaklık ise kış mevsiminde 4,7°C olarak 1. istasyonda ölçülmüştür. Tüm istasyonlarda sıcaklık değişim grafiği mevsimlerden bağımsız olarak aynı eğimde değişim göstermiştir. Ankara Çayı’nın kaynağına yakın olan 1. istasyonda en düşük sıcaklık değeri ölçülürken, şehir merkezine veya sanayi tesislerine doğru ilerledikçe su sıcaklığının arttığı tespit edilmiş, Sakarya Nehri ile birleşme noktasına en yakın konumdaki 10. istasyonda ise en yüksek su sıcaklığı ölçülmüştür. Ankara Çayı’nda yapılan sıcaklık ölçümleri literatürde yer alan çalışmalarla paralellik göstermektedir.

pH, sucul sistemdeki fizikokimyasal ve biyolojik faktörleri değiştirerek suyun asitliğini ve alkalinitesini yansıtan bir parametredir. Ankara Çayı’nda en yüksek pH değeri ilkbahar mevsiminde 8,39 olarak, en düşük pH değeri ise yaz mevsiminde 7,46 olarak ölçülmüştür. pH değerleri Yerüstü Su Kalitesi Yönetmeliği (YSKY)’ne göre değerlendirildiğinde, I. sınıf, yüksek kaliteli sular sınıfa girdiği ve literatürde yer alan çalışmalarla paralellik gösterdiği saptanmıştır.

Çözülmüş oksijen derişimi ve doygunluğu parametreleri, suda çözünen moleküler oksijendi ifade etmekte olup içeriği, su kütlesinin kendi kendini arıtma yeteneğini ölçmek için bir göstergedir. Bu parametre, en düşük yaz mevsiminde 0,82 mg/L olarak 6. istasyonda (III. sınıf) ve en yüksek ise kış mevsiminde 10,32 mg/L olarak 1. istasyonda (I. sınıf) ölçülmüş, mevsimlere bağlı değişiklik gösterdiği tespit edilmiştir. Çözülmüş oksijen derişimi, sıcaklık ve basıncın bir fonksiyonu olduğundan ve sudaki biyolojik aktiviteyi etkilediğinden önemli bir parametredir. Sıcaklıkla orantılı olarak yaz mevsiminde çözülmüş oksijen değerlerinin azaldığı ve en yüksek değerlerin kış mevsiminde ölçüldüğü görülmektedir. Genel olarak mevsimsel değişim grafiklerinin birbirine paralel olduğu ancak tüm mevsimlerde 6. istasyondan itibaren çözülmüş oksijen değerlerinde düşme olduğu görülmekte olup, bu düşüşün nedeni olarak, bu istasyondan itibaren sanayi tesislerinin ve kentsel yerleşimlerin sayısının ve bu tesislerden/yerleşimlerden kaynaklanan kirlilik yükünün artmış olması gösterilebilir. Çözülmüş oksijen derişimi ve doygunluğu değerlerinin, YSKY’ye göre değerlendirildiğinde III. sınıf, orta kaliteli sular sınıfa girdiği tespit edilmiştir.

Nitrat (NO<sub>3</sub><sup>-</sup>), doğada var olan bitkiler için önemli bir besin kaynağıdır. Toprakla buluşarak sulara karışması; doğal veya suni gübre kullanımından, evsel veya endüstriyel atıksu deşarjlarından, septik tanklardan olabilmektedir. Nitrat parametresi, en düşük seviyede ilkbahar mevsiminde 0,065 mg/L olarak 10. istasyonda (I. sınıf) ve en yüksek seviyede ise kış mevsiminde 4,1 mg/L, olarak 1. istasyonda (II. sınıf) ölçülmüş, mevsimlere bağlı değişiklik gösterdiği tespit edilmiştir. Nitrat derişimi kış mevsiminde tüm istasyonlarda yüksek değerlerde seyrederken, diğer mevsimlerde 4. istasyondan itibaren düşüşe geçtiği görülmektedir. Nitrat derişiminin yüksek kaydedildiği istasyonların bulunduğu bölgeler, diğer istasyonlara nispeten sanayi tesislerinin daha az, tarım alanlarının daha çok olduğu bölgeler olması, nitrat kirliliğinin tarımsal faaliyetlerde kullanılan doğal veya suni gübrelerden veya evsel atıksu deşarjlarından kaynaklanabileceğini düşündürmektedir. Nitrat değerleri, YSKY’ye göre değerlendirildiğinde, kış mevsiminde 3. ve 4. istasyonlar (II. sınıf) hariç, diğer istasyonların tüm mevsimlerde I. sınıf yüksek kaliteli sular sınıfa girdiği tespit edilmiştir.

Şekil 1. Parametrelerin mevsimsel değişimi

Fosfor, sucul canlılar için mühim bir besleyici mineraldir ve doğal suların verimliliğini etkileyen önemli parametrelerden birisidir. Toplam fosfat parametresi, en düşük seviyede ilkbahar mevsiminde 0,066 mg/L olarak 1. istasyonda (I. sınıf) ve en yüksek seviyede ise sonbahar mevsiminde 2,59 mg/L olarak 10. istasyonda (III. sınıf) ölçülmüş, mevsimlere bağlı değişiklik gösterdiği tespit edilmiştir. Toplam fosfat analizlerine bakıldığında, yıllık ortalama ve mevsimlerdeki yükseliş trendinin 1. istasyonda en düşük seviyede iken 10. istasyona doğru arttığı görülmektedir. Her mevsimde özellikle 6. istasyondan sonra değerlerde ciddi bir artış görülmektedir. Toplam fosfat değerlerinin değişim grafiği, Ankara Çayı boyunca kirliliğin az olduğu yerden yoğun olduğu yere doğru besin girişi olduğunu göstermektedir. 6. istasyon yoğun sanayi tesislerinin ve evsel atıkların kaynaklandığı yerleşim bölgelerinin ortasında kalan bir konumdadır. Civarda Ankara Çayı'nın organik madde yükünü arttıran sanayi kuruluşlarının başında gelen süt ve süt mamulleri üreten tesisleri, entegre et ve tavuk işleme tesisi ve mezbahalar olması, aynı zamanda yakın bölgede hayvanat bahçesi ve evcil hayvan parkının varlığı, toplam fosfat kirliliğinin sanayi kaynaklı olmakla birlikte hayvansal atık kaynaklı olabileceğini de göstermektedir. Toplam fosfat değerleri, YSKY'ye göre IV. sınıf, zayıf kaliteli sular sınıfa girdiği tespit edilmiştir.

BOİ konsantrasyonu fazla olan bir çıkış suyunun oksijen tüketimi yeterince yüksekse yani anaerobik şartlara geçiyorsa, deşarj edildiği akarsuya zarar verebilmektedir. BOİ parametresi, en düşük seviyede kış mevsiminde 0,7 mg/L olarak 1. istasyonda (I. sınıf) ve en yüksek seviyede ise yaz mevsiminde 20,51 mg/L olarak 10. istasyonda (III. sınıf) ölçülmüş, mevsimlere bağlı değişiklik gösterdiği tespit edilmiştir. BOİ analizlerinde ölçülen değerler yaz mevsiminde yüksek seyrederken, diğer mevsiminde daha az ve aynı seviyede olduğu görülmüştür. BOİ değerleri YSKY'ye göre değerlendirildiğinde, III. sınıf, orta kaliteli sular sınıfa girdiği tespit edilmiştir. Ankara Çayı'ndaki organik kökenli kirliliğin yüksek olması sonucunda akarsuyun BOİ değeri de hatırı sayılır derecede yüksek olmaktadır.

Bulanıklık, suyun berraklık ve şeffaflığının bir ölçüsüdür. Bulanıklık parametresi, en düşük seviyede ilkbahar mevsiminde 3. istasyonda 0,42 NTU, en yüksek seviyede ise kış mevsiminde 9. istasyonda 175,5 NTU olarak ölçülmüş, mevsimlere bağlı değişiklik gösterdiği saptanmıştır. Kış mevsiminde yağışların etkisiyle her istasyonda bulanıklık değeri yüksek çıkarken, diğer mevsimlerde özellikle 7. istasyondan itibaren bulanıklık değerlerinde ciddi bir artış görülmektedir. Sanayi tesislerinin yoğun olduğu bu bölgedeki kirlilik durumu, her ne kadar diğer parametrelerdeki dalgalanmalar ile görülmekte ise de bulanıklık değerindeki artışın nedenlerinden birisinin de zemin farklılığından kaynaklandığı düşünülmektedir. Ankara Çayı ıslah çalışmaları kapsamında 7. istasyona kadar zeminin kaplamalı ve duvarların çift taraflı taş tahkimatlı, bu noktadan sonra zeminin toprak olduğu bilinmektedir.

Potansiyel patojen olan fekal koliformun standartları aşan miktarda bulunması, suyun dışkı ile kontamine olduğu ve enfeksiyon taşıdığı anlamına gelmektedir (Çiçek vd., 2017). Fekal koliform değerleri tüm sene boyunca bir istasyon hariç aynı olmuştur. Sadece ilkbahar mevsiminde 1. istasyonda 29/100 ml olarak ölçülmüş, diğer tüm mevsimler ve tüm istasyonlarda ölçülen fekal koliform değeri 1100/100 ml'den fazla olarak tespit edilmiştir. Potansiyel patojen olan fekal koliformun standartları aşan miktarda bulunması, suyun insan sağlığına zararlı olduğu anlamına gelmektedir. Elde edilen bu sonuçlara göre, Ankara Çayı'na kanalizasyon sisteminden sızıntı olabileceği ya da bölgedeki hayvancılık faaliyetlerinden dolayı hayvan dışkılarının Ankara Çayı'na bulaşmış olabileceği tahmin edilmektedir.

Ankara Çayı'nda dört mevsim ölçülen parametrelere göre su kalite indeksi hesaplandığında; (Şekil 2) en düşük NSF-WQI indeksi değeri kış mevsiminde 9. istasyon 37,07 (kirlili), en yüksek NSF-WQI indeksi değeri ise ilkbahar mevsiminde 80,86 (iyi) olarak 1. istasyonda ölçülmüştür.

Kış mevsimi su kalite indeksi değerleri

Sonbahar mevsimi su kalite indeksi değerleri

İlkbahar mevsimi su kalite indeksi değerleri

Su kalite indeksi değerlerinin mevsimlere değişimi

Yaz mevsimi su kalite indeksi değerleri

Ankara Çayı yıllık ortalama su kalite indeksi değerleri

Şekil 2. Ankara Çayı Su Kalite İndeksi Mevsimsel değerleri

2019 yılı kış, ilkbahar, yaz ve sonbahar mevsimleri su kalitesi sonuçları YSKY'ne göre değerlendirildiğinde; Ankara Çayı genel olarak "IV. sınıf" su kalitesinde, NSF-WQI su kalite indeksine göre değerlendirildiğinde ise su kalitesinin "kirli" olduğu tespit edilmiştir. NSF-WQI modeli uygulaması sonucu elde edilen veriler, her bir parametre için ulusal mevzuattaki su kalite standartlarıyla mukayese edildiğinde, sonuçların uyumlu ve gerçekçi olduğu görülmektedir. Bu da NSF-WQI modelinin Ankara Çayı üzerinde başarılı bir şekilde uygulandığını göstermektedir.

Türkiye'de pek çok akarsuda ciddi kirlilik sorunu yaşanmaktadır ve bu sorunun ortak nedeni arıtlımsızın alıcı ortama verilen atık sulardır. Su Havzaları, Kullanımı ve Yönetimi Özel İhtisas Komisyonu Raporu'na (2001) göre, Türkiye'nin en fazla kirlenmiş akarsularından biri olan Sakarya Nehri, Ankara Çayı, Porsuk Çayı ve Çark Suyu tarafından taşınan atık sular ile kirlenmektedir. Raporunda Ankara Çayı'nın, Ankara nüfusunun yaklaşık %90'ının evsel atık sularını Sakarya Nehri'ne taşıdığı ve IV. sınıf çok kirli sular kategorisinde olduğu ifade edilmektedir. Olumlu ve koruyucu önlemlerle su kütlelerinin potansiyel kirlilik riski etkili bir şekilde önlenilmekte, yüksek kaliteli ve güvenli bir içme suyu kaynağı sağlanabilmekte ve su ortamının sürdürülebilir gelişimi korunabilmektedir (Zhan vd., 2021). Su kaynaklarının kirlenmesinin önlenmesi, kirlenmiş suların arıtılmasından daha ekonomik olduğundan hem ulusal hem de bölgesel anlamda kirliliğe neden olan hammadde, proses, tesis vs. tüm kaynakların belirlenerek engellenmesi ve su kaynaklarının kontrol altına alınması gerekmektedir (Turan ve Ülkü, 2013). Su kaynaklarını kirlenmeden önce gerekli koruyucu ve önleyici tedbirler almak gerekmektedir.

Ankara Çayı su kalitesinin iyileştirilmesi için öncelikle kirlilik kaynaklarının akarsuya ulaşmasının engellenmesi gerekmektedir. Tarım arazilerinde bilinçsiz ve denetimsiz kullanılan tarım ilaçlarından kaynaklanan kirliliğin yanı sıra bazı bölgelerde kanalizasyon atıklarının Ankara Çayı'na deşarj edildiği veya kanalizasyon sistemindeki kaçaıklardan dolayı sızıntıların olduğu bilinmektedir. Bu kirlilik yükü Ankara Çayı su kalitesinin kötü olmasının en önemli sebeplerinden birisidir. Yapılması gereken ilk çalışma, Ankara Çayı üzerinde bulunan kaçak deşarj noktalarının tespit edilerek önlenmesi olacaktır.

Diğer yandan, Ankara Çayı'na deşarj eden atıksu arıtma tesislerinin deşarj kriterleri yeniden gözden geçirilmeli ve deşarj edilen arıtılmış su kalitesi denetlenmelidir. Bilindiği üzere, ASKİ'ye ait birçok atıksu arıtma tesisi ve organize sanayi bölgelerindeki arıtma tesisleri arıtılmış suları Ankara Çayı'na deşarj etmektedir.

Ankara'da faaliyetleri sonucu belli bir miktarın üzerinde atıksu elde eden sanayi tesisleri bir araya getirilip, Ergene Havzasında olduğu gibi ıslah OSB'ler kurulması ve sanayide daha az su, daha az enerji, daha az kirlenici hammadde kullanılmasına yönelik proseslerin geliştirilmesi ve Ar-Ge çalışmalarının yapılması önerilmektedir. Atıksu Arıtma Tesislerinin ve Organize Sanayi Bölgelerinin atıksu arıtma sistemleri periyodik olarak denetlenmeli, Ankara Çayı'na deşarj edilen arıtılmış su kalitesinin yüksek seviyede olması sağlanmalıdır. Ayrıca OSB'lerde arıtılan suların tekrar OSB'deki tesislerde kullanılmasının sağlanabileceği ileri arıtma sistemlerinin kurulması ve işletilmesi teşvik edilmelidir.

Sonuç olarak yapılan bu çalışmada, Ankara Çayı su kalite indeksi belirlenmiş, Ankara Çayı'nın su kalitesinin NSF-WQI kalite indeksine göre "kirli" olduğu tespit edilmiştir. NSF-WQI modeli uygulaması sonucu elde edilen veriler, her bir parametre için ulusal mevzuattaki su kalite standartlarıyla mukayese edildiğinde, sonuçların uyumlu ve gerçekçi olduğu görülmektedir. Ankara Çayı üzerinde kirlilik baskısı oluşturan; tarım arazilerinde bilinçsiz ve kontrolsüz kullanılan kimyasal gübrelerin kontrol altına alınması, şehrin kanalizasyon sistemindeki kaçaıkların tespit edilerek engellenmesi, atıksu arıtma tesislerinden deşarj edilen arıtılmış suların periyodik olarak denetlenmesi durumunda Ankara Çayı su kalitesinde iyileşmeler hemen görülecektir. Sakarya Nehri'nin önemli bir parçası olan Ankara Çayı, bölgedeki kirlilik yükünü tüm havzaya taşıdığından, ivedi bir şekilde uygulanabilir tedbirleri alınması hem Ankara Çayı hem Sakarya Havzası için önem arz etmektedir.

## POSTER PRESENTATION

### Pharmaceutical aspects of drugs used in pathologies of the cardiovascular tract

Klodiola Dhamo\* (ORCID: <https://orcid.org/0009-0004-6422-7471>)

\*<sup>1</sup> Aldent University, Faculty of Medical Sciences, Department of Pharmacy, Tirana, Albania.

#### Abstract

Cardiovascular diseases (CVD) are a medical, social and economic problem. Their treatment today accounts for nearly 80% of the world's health expenditures. The treatment regimens for these diseases often include several drugs that can affect each other's effect. Diseases of the cardiovascular tract are the most frequent and life-threatening pathologies.

The aim of this study is to gain an overview of the diseases and their pharmacological treatment, to determine the prescription patterns of antihypertensive drugs and time trends among diagnosed cases of hypertension, and to investigate the pharmaceutical costs associated with different antihypertensive agents.

The study was carried out in the city of Korça, (for a period of two months), included patients treated for the disease of arterial hypertension, angina pectoris, ischemic heart disease, etc. 348 recipes were analyzed for the period November, December 2022. A total of 348 patients diagnosed with cardiovascular tract diseases (SCV), aged  $\geq 50$  years, were identified from the study population of 4000 patients in the computerized reimbursement database of the Health Insurance in the city of Korça.

The data were processed statistically. Data on age, category, dose/prescription, dose/total, reimbursement per prescription were obtained. The frequency encountered of each drug used and the direct cost of treatment were calculated.

Patients who receive drug treatment with arterial hypertension diagnosis have a higher number of medications for the cardiovascular tract with 65.5%. The smallest number with only 9.78% was occupied by patients treated with drugs for the diagnosis of Angina pectoris. The most frequently prescribed antihypertensive drug is Hydrochlorothiazide 25mg, which has the highest prescription frequency with 32.58%, while the lowest prescription frequency is Furosemide 40mg with 9.67%.

**Keywords:** *Diseases of the cardiovascular tract, diagnosis, drugs, patients, costs*

#### INTRODUCTION

Treatment of patients with hypertension is carried out by means of drugs as well as following the advice of specialists on lifestyle, nutrition and physical activity.

Some drugs are more effective in treating hypertension and have different good or side effects in patients..

The mortality rate from ischemic heart disease attributable to hypertension has doubled in Albania over the past 20 years, while the death rate from cerebrovascular diseases due to arterial hypertension has increased by more than 70%.

Hypertension is the most common disease and costs the most in terms of medications, which are covered by both the Insurance and Health Care Institutes.

Pharmacists intervention can modify factors associated with compliance, improve compliance in achieving the goal of lowering blood pressure in patients treated with antihypertensive agents.

#### MATERIALS AND METHODS

The study was carried out in the city of Korça, (for a period of two months), included patients treated for the disease of arterial hypertension, angina pectoris, ischemic heart disease, etc. 348 recipes were analyzed as a representative sample for the period November-December. A total of 348 patients diagnosed with cardiovascular tract diseases (SCV), aged  $\geq 50$  years, were identified from the study population of 4000 patients in the computerized database of Health Insurance reimbursements in the city of Korça.

The data were processed statistically. Data on age, category, dose/prescription, dose/total, reimbursement per prescription were obtained. The frequency encountered of each drug used and the direct cost of treatment were calculated

To prevent possible confounding by comorbidities in prescription patterns of antihypertensive agents, patients diagnosed with ischemic heart disease, pulmonary circulation disease, other forms of heart disease (including dysrhythmia and heart failure), stroke or kidney, were excluded from the study sample.

Six major classes of antihypertensive drugs are generally available, including angiotensin-converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), beta-blockers, calcium channel blockers (CCBs), diuretics, and others (all other antihypertensive classes including alpha-blockers).

Prescriptions for a chronic disease in Albania, such as hypertension, most often included the prescription of drugs for 28-180-day periods, which would allow the patient to see a doctor every one to six months. As each prescription could contain different drug combinations and duration of medication, data analysis was undertaken using the prescription rate, calculated as the number of prescriptions containing a specific antihypertensive agent divided by the total number of prescriptions.

## RESULTS

**Table 1.** Distribution of patients by age group in number and percentage, who use reimbursed drugs for the treatment of cardiovascular tract pathology.

Age	Nr of patients	Age in %
51-60	15	4.40
61-70	81	23.30
71-80	137	40.50
81-90	113	31.20
91-100	2	0.60

**Table 2** Distribution of patients by gender in number and percentage, who use drugs with reimbursement, for the treatment of cardiovascular tract pathology

Gender	Nr of patients	%
Female	219	63
Male	129	37

**Table 3** Distribution of patients according to the type of diagnosis of the cardiovascular tract medication

Diagnostic	Nr	%
AHT	228	65.5
Arithmia	43	12.35
Arteriosklerosis	43	12.35
Angina pectoris	34	9.78

**Table 4** Distribution of patients according to concomitant diseases

Diagnostic	Co-occurring diseases	%
AHT	82	71.9
Arithmia	1	0.87
Arteriosklerosis	7	6.14
Angina pectoris	3	2.63
Fat metabolism disorder	21	18.4

**Figure 1** Distribution of the 10 most frequently prescribed antihypertensive drugs, ordered by frequency of prescription

**Figure 2** Distribution according to the 7 most frequently prescribed antihypertensive regimens, ordered by frequency of prescription

**Table 5** Distribution of categories of pensioners by gender.

Gender/categoria	Permanent pensioner	Totally disabled
Female	204 (62.74%)	2 (50%)
Male	121 (37.26%)	2 (50%)

**Table 6** Average cost distribution for each diagnosis

Diagnostic	AHT	Arithmia	Angina pectoris	Arteriosclerosis
Average cost for prescriptions	487.34 Lek	911.95 Lek	435 Lek	263.61 Lek
Average cost in percentage	23.22%	43.46%	20.78%	12.56%

## CONCLUSION

Patients who receive treatment for drugs with HTA diagnosis have a higher number of medication for the cardiovascular tract with 65.5%. The smallest number with only 9.78% was occupied by patients treated with drugs for the diagnosis of Angina pectoris.

The co-morbidity encountered most often in patients is HTA with 71.9%. While the less frequently encountered co-morbidity is heart disease with 0.87%.

The most frequently prescribed antihypertensive drug is Hydrochlorothiazide 25mg, which has the highest prescription frequency with 32.58%, while the lowest prescription frequency is Furosemide 40mg with 9.67%.

Females have the highest tendency for the category "Pensioner without term" with 62.74%. "Chronic patients" women occupy the largest part with 68.43%, while men make up the smallest number with 31.57%.

Diagnosis Heart rhythm disorder has the average cost of treatment of the highest diagnosis worth 911.95 Lek. The average cost per prescription is 650.94 Lek. The smallest reimbursement cost per prescription is 90 Lek for the drug Metoprolol 100mg.

The value of the prescription with the highest reimbursement cost belongs to the category of the disease Heart rhythm disorder with a value of 5800 Lek with the drugs Rivaroxaban Fenofibrate 200mg and Metoprolol 100mg.

#### Abstract

This study aims to determine the chemical composition of the essential oil of *Myrtus Communis* and the evaluation of its antibacterial activity. The extraction of essential oils was carried out by hydro distillation of the aerial parts. The chemical composition of the oils obtained was carried out using GC/MS chromatographic techniques, while the microbiological study was evaluated by the disk diffusion method on 13 pathogenic strains including gram (+) and gram (-).

The results obtained showed that the essential oil of *Myrtus Communis* is characterized by the presence of: alpha-pinene (49.93%), D-limonene (6.42%), Eucalyptol (34.46%), Linalool (2, 84%) , alpha-terpineol (2.33%) as main constituents. The antibacterial effect determined by the disc diffusion method showed that our oil proved to be inactive on all the strains tested except for two strains *Staphylococcus aureus* and *Proteus mirabilis* with an inhibition diameter of 15 and 13mm respectively.

**Keywords:** communist; essential oil; CPG/MS-; antibacterial activity

**Introduction :** The myrtle (*Myrtus communis*) is a shrub of the Myrtaceae family of which it is the type. The name of the myrtaceae comes from the myrtle (genus *Myrtus*) the only European survivor of this vast family which, having been eliminated from Europe by the glaciations, found refuge in the tropical and subtropical regions of the globe.

Rich in essential oil, this species used in cooking has therapeutic virtues as an antiseptic, antispasmodic, anti-inflammatory...

The objective of this study is the valorization of Myrtle through the analysis of its essential oil and the evaluation of its antifungal and antioxidant activity.

#### MATERIALS AND METHODS:

1/ Plant material

The drug: dried leaves of *Myrtus communis*.

Harvest time: March (before flowering).

Provenance: Seraidi. wilaya of Annaba. Algeria.

2/ Extraction and identification of the essential oil

Extraction of essential oil from myrtle leaves was carried out by steam distillation for 3 hours. The average yield is 1.14ml per 100gr of dried leaves.

The identification of the chemical components of H.E. is carried out by GC/MS of the clarus 600 D Perkin Elmer type. The column used is a RESTEK Rtx®-5MS (30 meters in length, 0.25 mm internal diameter, film thickness is 0.25 µm).

A splitless injection mode is used. Helium was used as carrier gas at a flow rate of 1ml/min. The injector and transfer line temperatures were increased to 250°C. The initial temperature was maintained at 60° C. for 1 minute, then increased by 3° C. per minute to reach 200° C. and is maintained under isotherm for 13 minutes. The volume injected was 1 µL. The standard solutions and the essential oil were diluted in absolute alcohol (1g/L).

Analyzes were performed in electron impact ionization (E-I) mode with an ionization energy of 70 eV using Scan mode acquisition (from 40 up to 600 $\mu$ ).

The identification of the compounds was made by comparison of the retention times, on the one hand, of the samples, and on the other hand, of the standard solutions, then by comparison of the mass spectra with those contained in the NIST® commercial library (National Institute of Standards and Technology).

The percentage of each compound is calculated by the internal normalization method.

### 3/ Evaluation of antifungal activity:

The antifungal activity is measured by the tube dilution technique on the reference strain *Candida albicans* ATCC 10231. The culture medium used is liquid Sabouraud Chloramphenicol. After incubation for 24 h at 35°C, the absorbance is measured at 560 nm.

The experimental data is subjected to statistical analysis. The graphical representation of the inhibition of fungal growth as a function of the concentration of essential oil presents a hyperbolic aspect with the equation  $y = ax / (b+x)$ . The use of an adjustment software makes it possible to determine the parameters a and b from which one will deduce the MIC 80% which characterizes the antifungal activity, and the constant of affinity Kaff (1/b) of the antifungal for yeast.

Parameter a: calculated maximum inhibition.

Parameter b: concentration of antifungal that induces a calculated inhibition equal to half of the calculated maximum inhibition.

### 4/ Evaluation of the antioxidant activity:

The antioxidant activity of the essential oil is measured by the ferric iron reduction method. The reducing power of ferric trichloride is determined by the following method reported by Zhao et al:

-100 $\mu$ l of essential oil is mixed with 2.5ml of phosphate buffer (pH 6.6) and 2.5ml of 1% ferricyanide.

-the mixture is incubated at 50° C. for 20 minutes. To the latter, 2.5 ml of 10% trichloroacetic acid is added followed by centrifugation at 3000 rpm for 10 minutes.

-5ml of supernatant is taken and then mixed with 5ml of distilled water and 1ml of 1% ferric trichloride

\_The absorbance is then measured at a wavelength of 700nm. The final result of this measurement is expressed in  $\mu$ g of ascorbic acid equivalent / g of dry weight

## RESULTATS :

1/ GC/MS analysis gave the following results:

The main constituents of H.E. are shown in the following table

N°	Denomination	Teneur en %
1	Alpha-pinene	49,93
2	D-limonene	6,42
3	Eucalyptol	34,46
4	Linalol	2,84
5	Alpha-terpineol	2,33
6	5-tetradecene	0,69
7	Geranyl-acetate	2,03
8	Eugeanol methyl ether	1,30

2/The antifungal action of H.E. myrtle on a strain of *Candida albicans* gave a low MIC value: 18.87 $\mu$ l/ml for a Kaff of around 0.11

3/the antioxidant activity measured by the iron reduction method (FRAP) revealed moderate activity with an EC50= 3.26mg/mL.

### Conclusion:

Thanks to GC/MS applied to the analysis of H.E. of *Myrtus communis*, 8 major constituents have been identified, the most important being: alpha-pinene (49.93%), eucalyptol (34.46%), and D-limonene (6.42%). In parallel, this H.E. is endowed with a significant antifungal action against *Candida albicans* due to its richness in oxygenated compounds. This could justify its use for the treatment of dermatoses of fungal origin.

#### Abstract

The present study took place in the Middle Oued Righ, where we conducted an inventory of plants located in this Saharan area. For this, we used satellite imagery to choose study sites. Followed by floristic surveys according to subjective sampling. The identification of vegetation areas in the Middle Oued Righ was conducted through the visual interpretation of the color composition of the spectral bands (blue, green and red) and spectral analysis by N.D.V.I. The results identified 9 stations covering 6 geomorphological sites. Floristically, there are 91 registered plant species. These cover 28 families but the Asteraceae family is the most representative and the Saharo-Sindian element is the most remarkable. The plateaus, the ergs and the hills constitute the most floristically rich geomorphological sites compared to the sebkha, the lake and the wadi in the Middle Oued Righ area.

**Keywords:** Saharan species, remote sensing, vegetation zone, Middle Oued Righ, Central Northern Sahara.

#### INTRODUCTION

Algeria from West to East and from North to South is characterized by its great geographical, bioclimatic, geological, geomorphological and edaphic diversity at the origin of a considerable ecosystem and floristic richness. This diversity has aroused the interest of many researchers and work on the organization, dynamics and functioning of forest species that have emerged.

Indeed, in the Algerian South where the Sahara is precisely the northern Sahara, the Saharan vegetation carpet is discontinuous and very irregular; the plants especially use the locations where the water is a little more accessible than elsewhere. The vegetation of the arid zones, in particular those of the Sahara, is very sparse, with a generally bare and desolate appearance, the trees are as rare as scattered and the grasses appear there only for a very brief period of the year, when the climatic conditions become favorable (Quézel, 1965 and Ozenda, 1982)

Currently, the ecological balance that has lasted for centuries is broken due to desertification and climate change. Also, by browsing the ecosystems of the northern Sahara, their apparent homogeneity actually hides a great heterogeneity in detail (Hadjajidi-Benseghier et al., 2017).

The objective of this study is to identify vegetation zones using the remote sensing tool which allows us to acquire more information about a given area. As well as; the identification of the floristic composition of spontaneous plants; populating the ecosystems of the northern Sahara in Algeria (case of the Middle Oued Righ).

## MATERIALS AND METHODS

### 1. Presentation the Middle Oued Righ

The Middle Oued Righ represents the central part of the Oued Righ Valley which consists of 3 zones: Upper, Middle and Lower Oued Righ. This valley is located in the northeast of the Algerian Sahara between the northern latitudes " 32°45'-34°30' " and the longitudes Are "5°45'-6°15' ". It is an elongated depression (gutter-shaped) from south to north along the great Eastern Erg extending over a length of 150 Km and a width of 15 to 30 Km (Figure 1 and 2).

The Middle Oued Righ corresponds to the area that extends from the south of Ain Shusha to the North of Tinedla (Figure 2). As, it is known by the palm groves of Sidi-Amrane, Skhouna, Ayata, Tamerna-Djedida, Tamerna-Guedima, Chmarra, Shusha, Djamaa, Ourlana, Tigdidine, Sidi-Yahya, Mazheur, Zaouiat-Riab, El-Arifiane and Tinedla .

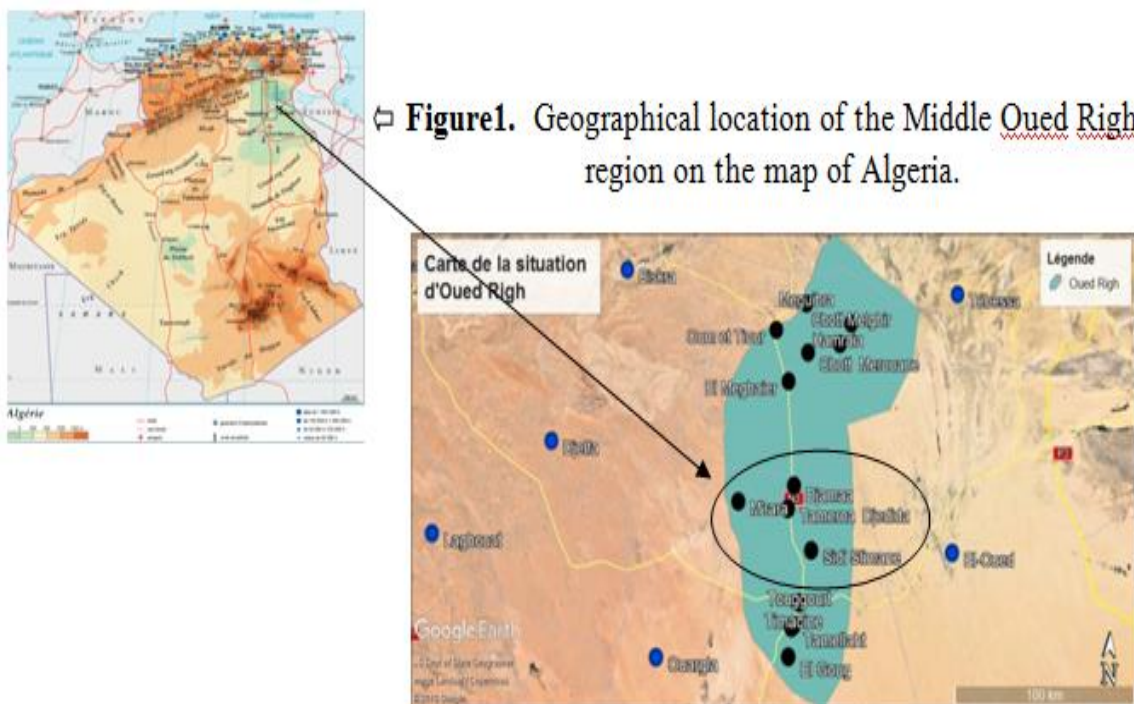

Figure 1. Geographical location of the Middle Oued Righ region on the map of Algeria.

Figure 2. Satellite image of the Oued Righ and Middle Oued Righ region (1/1500); (Google Earth,2018)

### 2. Methodology

Our methodology consists of three stages; which are:

1. Remote sensing prospecting, which involves two phases:
  - a. Visual analysis: (colored composition)
  - b. Spectral analysis: (normalized Difference vegetation index: N D V I)
2. Choice and establishment of the map of the study stations
3. The Floristic analysis (Sampling and Floristic Inventory)

## Results

### Image processing "SENTINEL-2" by ENVI 4.7 and geo-location of study stations

In order to properly explore the vegetation of the study area, we used satellite imagery. To this end, our investigations concerned (i) the colored composition, (ii) the standardized vegetation index "NDVI" and (iii) topographic maps for the geo-location of the study stations.

#### 1. Interpretation of the colored composition of the "SENTINEL-2" image of the study area

The colored composition of the "SENTINEL-2" image of the Middle Wadi Righ was made from the Blue, Green and Red spectral bands (Figure 4a), because it is the most representative for the study area and the closest to the real colors. Indeed, we can clearly distinguish the different formations such as :

- the vegetation is dark green in color ;
- the dark brown to black depending on the degree of humidity represents the wetlands (wadi and lakes) as well as the canal ;
- the sands and the sandstones represent the colors ranging from beige to light brown respectively ;
- a large area colored in light to dark cyan also showing areas of efflorescence of salt crystals and saliferous crusts depending on the degree of humidity and the level of salinity (dry salty soil and wet salty soil).

#### 2. Spectral index: normalized Difference vegetation index (NDVI)

Through this index, a good visualization is obtained for the vegetative zones; of which they appear in white for the strong chlorophyll activities.

The presentation of the NDVI image (Figure 4 b) obtained after the analysis of the satellite image of the "Middle Wadi Righ" study area using the ENVI 4.7 software; and comparing with the map of the Middle Wadi Righ region (Fig. 9), shows the following :

- the white color represents the palm trees of Djamaâ and M'rara where the vegetation cover is relatively dense ;
- the light gray color which means the dense vegetation cover; it represents the vegetation of the wetlands precisely of Wadi R'tem and lakes Ayata and Djamaâ ;
- the less dense vegetation cover is indicated by the gray color. It represents the spontaneous plants that are found at the level of the plateaus and ergs ;
- the dark color represents the absence of vegetation in the depressions.

Figure 3. Map of the Middle Oued Righ region

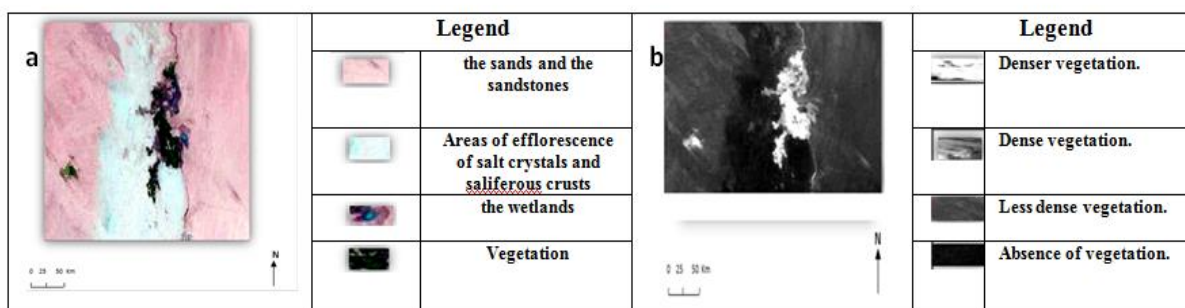

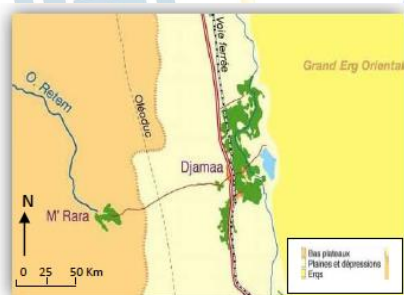

Figure 4.(a) Composition colorful from the spectral bands blue, Green and Red image "SANTINEL-2" of the 03/03/2018 and (b) the image of the index NDVI of the Middle Oued Righ region.

By using the topographic maps of Ghardaïa and Touggourt as well as ArcGIS version 10.1 software, we were able to establish the sampling map (Figure 5) At the level of the latter, we have geolocated the study stations, which are nine in number, by a field GPS and Google Earth pro.

Figure 5. Location of study stations on the topographic map

On this map (Figure 5), we have represented the sites that are potentially floristically rich in the Middle Wadi Righ. This guided us in our approach to floristic study.

#### Floristic Inventory

The floristic inventory carried out at the level of the Middle Wadi Righ, allowed us to register 91 plant species. These cover 60 genera and 28 families (Table1).

Table 1. Species inventoried according to the different families.

The rates of these families vary widely ( Figure 6). Among the most abundant families, we note in descending order, the Asteraceae family with 17.58% (16 species), the Brassicaceae with 12.09% (11 species) and the Amaranthaceae with 8.79% (08 species).

Figure6 . Proportion of families listed the Middle Oued Righ

The distribution of species according to the sites shows that it is variable. Indeed, we note in the most diversified site the plateau 21 families and 66 species; of which the dominant family is that of the Asteraceae with 10 species which are *Brocchia cinerea* (Delile) Vis., *Cotula anthemoides* L., *Heteromera fuscata* (Desf.) Pomel, *Ifloga spicata* (Forssk.) Sch. Bip, *Launaea angustifolia* (Desf.) Kuntze, *Launaea capitata* (Spreng.) Dandy, *Launaea capitata* Sp., *Launaea mucronata* (Forssk.) Muschl., *Launaea quercifolia* (Desf.) Pamp.,

*Launaea fragilis* (Asso) Pau ; followed by the Erg with 16 families and 53 species; of which the dominant family is that of the Asteraceae with 9 species which are *Atractylis carduus* (Forssk.) V. Chr., *Brocchia cinerea* (Delile) Vis. , *Cotula anthemoides* L., *Launaea capitata* (Spreng.) Dandy, *Launaea nudicaulis* (L.) Hook. F., *Launaea fragilis* (Asso) Pau , *Launaea fragilis* sp , *Picris asplenioides* L. and *Picris* sp; and the hills with 13 families and 25 species; of which the dominant family is that of the Boraginaceae with 6 species which are *Echium horridum* Batt. , *Echium humile* Desf. , *Echium humile* subsp. *pycnanthum* (Pomel) Greuter & Burdet, *Echium trygorrhizum* Pomel, *Moltkiopsis ciliata* (Forssk.) Johnst and *Ogastemma pusillum* (Bonnet & Barratte) Brummitt. . While the sites of Wadi, sebkha and the lake are the poorest in species. With 13 families and 16 species in the Wadi, of which the Amaranthaceae, Asteraceae and Tamaricaceae families are equal; 4 families and 4 species at the sebkha which are Amaranthaceae (*Halocnemum strobilaceum* (pall) M. Bied. ); Juncaceae (*Juncus maritimus* Lam. ); Poaceae (*Phragmites communis* Trin ) and Tamaricaceae (*Tamarix gallica* sp) and the lake site with 6 families and 9 species of which the dominant family is that of the Amaranthaceae with 4 species which are *Halocnemum strobilaceum* (pall) M. Bied. , *Sarcocornia fruticosa* (L.) A.J. Scott , *Suaeda vermiculata* Forssk. ex J.F. Gmel. , *Traganum nudatum* Del.

The phytogeographic spectrum shows a very significant diversity of phytogeographic elements in the study region .Indeed, the Saharo -Sindian element dominates the Wadi Righ area with 34 species, and the endemic element comes in second position with 31 species ahead of the Mediterranean element which includes with 17 species.

## DISCUSSION

The use of remote sensing through the "SENTINEL-2" image of the Middle Wadi Righ, led us to better explore the study area. Indeed, It appears that through the colored composition, we can observe that the cultivated plants (palm trees) in dark green color; whereas the spontaneous plants are not observed because of their low spectral reflectance, which poses a disadvantage. However, the spectral analysis of the satellite image by the normalized vegetation index (NDVI) makes it possible to obtain a good visualization for the vegetated areas of the study area. It appears in white for the strong chlorophyll activities.

However, it should be noted that the presentation of the NDVI image applied to the Wadi Righ Medium shows that there is a low spectral reflectance in the middle of the study area compared to these two East and West sides. This probably comes back to the high salinity levels characterizing the center of the study area. Mougénot B. (1993) demonstrated that when the salt level is high, it negatively affects the reflectance of vegetation.

The floristic inventory has allowed us to draw up a list of 91 plant species, covering 28 families where the Asteraceae family is predominant. The plateaus, the ergs and the hills constitute the most floristically rich geomorphological sites compared to the sebkha, the lake and the wadi in the Middle Wadi Righ area. Thus, our results are in accordance with those of Kherraze M.E., et al. (2010). However, in the Ouargla region (Chehma et al., 2005) as well as in the Central Sahara (Benhouhou and Benghanem, 2013), it is rather the wadis, lakes and dry valleys that are the most floristically rich. This seems obvious given the degree of aridity (Benseghier-Hadjaidji, 2018).

The phytogeographic spectrum shows a very significant diversity of phytogeographic elements in the study region. Indeed, the Saharo -Sindian element dominates the Wadi Righ area with 34 species, and the endemic element comes in second position with 31 species ahead of the Mediterranean element which includes with 17 species. It should be noted that most of the sampled species live in isolated areas. The distribution of spontaneous flora in this arid zone is usually due to chance it remains, however, rarely contagious. Indeed, no species adopts a regular distribution because of the heterogeneity of the environment (BAAMEUR, 2021).

## Conclusion

The present study focused on the application of remote sensing for the study of the floristic composition at the level of the Middle Oued Righ which is located in the central northern Sahara. Indeed, this study made it possible to conclude the following:

The identification of the vegetation zones in the study area was carried out thanks to the visual interpretation of the colored composition of the spectral bands (blue, green and red) as well as to the spectral analysis by N.D.V.I. The results obtained highlight 6 geomorphological sites covering 9 stations.

The floristic analysis allowed us to identify 91 plant species, covering 28 families but the Asteraceae family is the most representative and the Saharo –Sindian element is the most remarkable. The plateaus, the ergs and the hills constitute the most floristically rich geomorphological sites compared to the sebkha, the lake and the wadi in the Middle Oued Righ area.

#### Abstract

The increase in demands for well-being, especially in recent decades, has led to an intensive use of land but also to an increase in industrial production. Both of these factors are related to the use of large amounts of water, therefore taking measures to have sufficient and quality water suitable for human and industrial consumption but also for agriculture (irrigation) is part of environmental policies. all over the world.

In this paper, a quality assessment of the water of the river Shkumbin, Albania, based on the physical and chemical parameters, has been carried out. In the study, the physico-chemical parameters of eight water samples, taken along the course of the river, were analyzed. The analyzed parameters are ten: pH, EC, T, DO, TDS, Nitrite ( $\text{NO}_2^-$ ), Nitrate ( $\text{NO}_3^-$ ), Ammonia ( $\text{NH}_4^+$ ), salinity, and phosphates.  $\text{PO}_4^{3-}$ . The obtained data were subjected to statistical processing, with the aim of determining the polluted areas and sources of pollution. The watershed of the Shkumbin river is located in central Albania, and the sources of pollution are anthropogenic related to agricultural and industrial activity, but also natural related to the rock formations that lie in this basin and erosion.

The evaluation of the water quality of the river Shkumbin was carried out by comparing our parameters with those according to the WHO.

**Keywords:** pollution, water quality, physico-chemical parameters, irrigation, anthropogenic activity.

#### INTRODUCTION

Rivers and lakes are important sources of surface water. Albania is rich in many rivers and lakes which are used both for irrigation and fishing (Dreschel and Evans, 2010). The early urban centers were created by humans near the rivers, where river waters have been used for cleaning and other domestic purposes, as there were also the conditions for providing food (M.E.A. 2005). Rivers make up 1% of the planet's fresh water. In modern times, the industrial development and urbanization of society has led to the creation of large industrial and urban centers as well as the development of intensive agriculture. This has led to an increase in the need for fresh water, but at the same time also the pollution of river waters. The main sources of pollution are the anthropogenic ones related to industrial activity or urban discharges. Industrial waste and from excessive human activities that affect their physico-chemical characteristics which result in harmful effects on aquatic organisms. (Murhekar, 2011)(Vassilis et al., 2001). The discharge, in a continuous manner, into the waters of the rivers of the sewage of untreated cities, is the main problem of underdeveloped and developing countries (Singh, 2007). At present, more than 80% of the sewage generated in developing countries is discharged untreated into the environment, and about 50% of the population depends on polluted water sources for various uses, including irrigation (UNESCO 2003). Another potential polluter remains agriculture as a result of the use of fertilizers and pesticides, but also the discharges of livestock farms (Nahar et al., 2016). Water is the main component of living organisms, so their survival depends on water quality (Almeida et al., 2017). The assessment of water quality includes the assessment of its physio-chemical and biological parameters. Changes in parameters such as pH, salinity, DO, temperature, significantly affect the life of the water body (Kolawole et al., 2011)( Smitha et al., 2007). So the evaluation of the physico-chemical parameters gives us information about the pollution of the water body, the further study of this pollution is carried out with biological evaluations (Mali and Shumka 2012).

Natural pollution is related to the erosion of the soil on the banks of the rivers, but also from the rains, as well as the nature of the rock formations of the catchment area of the rivers. The nature of the mineralogical composition of the rocks of the watershed affects the values of parameters such as pH, EC or TDS. (Bucher et al, 2017).

In general, the parameters of surface bridges change according to the seasons, dry or wet, but also the change of agricultural activity in different seasons (Uddin et al., 2016)

## MATERIALS AND METHODS

### Study area:

Shkumbin River is one of the main rivers of Albania with a length of 181.4 km and a catchment area of 2445 km (fig 1) and an average height of the water flow of 753.2 m. This shows that the Shkumbin river is a fast-flowing river, as a result, in the rainy season, it causes high erosion, causing its pollution.

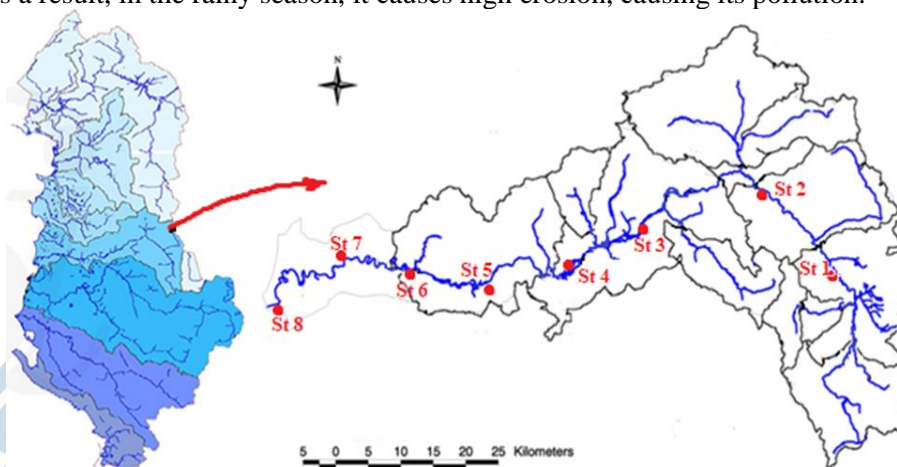

Figure 1. Shkumbin river catchment basin.

The river flows fluctuate a lot depending on the seasonality, the annual mean of the flows is 61.5 m<sup>3</sup>/s and the total annual amount of sediments 7.2 · 10<sup>6</sup> tons/year (Pano et al., 1984)

**Sampling:** Samples were taken during the month of June 2023, almost along the entire length of the river at 8 sampling stations (fig1). Water sampling was done with 0.5 liter plastic bottles. The bottles were first washed with distilled water and then rinsed with 10 ml of 2% HCl. Before being filled, the bottles were again washed several times with river water and filled to the brim with the water sample, eliminating the existence of air bubbles in the bottles. and are closed with a safe cork, providing them with the appropriate label. Afterwards samples were transported to the lab within the same day using cooling boxes to keep the temperature of +4°C. The samples were stored under standard conditions till the analysis. Temperature, pH, conductivity (CE), dissolved solids (TDS), salinity and dissolved oxygen (DO) was measured directly with camera multimeter Hach (Sension 156). The concentration of nutrients (NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, PO<sub>4</sub><sup>3-</sup>) was performed with UV–VIS spectrophotometer PYE UNICAM SP6 - 550, respectively at 543nm, 220 - 270nm, 630nm and 880nm.

## RESULTS and DISCUSSION

The values of the ten parameters obtained from the analysis of 8 water samples of the Shkumbin River are summarized in a data matrix and descriptive statistics were used to interpret the results and to explain the data variations. The values of the statistical processing of the data are presented in table 1.

As can be seen from table 1, the median values for the physico-chemical parameters in the Shkumbin river are within the values recommended by WHO.

**Table 1.** Descriptive Statistics: pH, Temp, EC, DO, TDS, NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, PO<sub>4</sub><sup>-3</sup>, Salinity.

Variable	Unit	Mean	StDev	CoefVar%	Minimum	Median	Maximum	WHO
pH		8.1675	0.2449	3.00	7.7400	8.1900	8.5500	6.5-8.5
Temp	°C	21.362	2.356	11.03	18.500	20.550	24.700	<40
EC	uS/cm	351.13	26.05	7.42	329.00	341.00	398.00	750
DO	mg/L	9.238	1.060	11.47	7.900	9.100	10.800	> 5
TDS	mg/L	157.69	11.75	7.45	140.40	162.85	171.30	1000
NO <sub>2</sub> <sup>-</sup>	mg/L	0.03275	0.01597	48.77	0.00600	0.03550	0.05200	< 3
NO <sub>3</sub> <sup>-</sup>	mg/L	1.526	0.324	21.21	0.810	1.560	1.880	50
NH <sub>4</sub> <sup>+</sup>	mg/L	0.2437	0.1462	59.97	0.0500	0.2200	0.5400	0.5
PO <sub>4</sub> <sup>-3</sup>	mg/L	0.02500	0.01742	69.68	0.00500	0.02400	0.05700	0.3
Salinity	mg/L	0.06525	0.02307	35.36	0.04500	0.05700	0.11000	250

The coefficient of variation (CV) is the ratio of the standard deviation to the mean. The higher the coefficient of variation, the greater the level of dispersion around the mean. The high CV values of some parameters such as salinity, NH<sub>4</sub><sup>+</sup>, PO<sub>4</sub><sup>-3</sup>, NO<sub>3</sub><sup>-</sup> show that we have an anthropogenic impact on the river water quality. The parameters for which the CV changes a little, that is, in the stations along the course of the river there are no significant differences, the anthropogenic influences are smaller.

Fig. 2 shows the probability of occurrence of the values of the studied parameters. The slope of the graphs for parameters such as NO<sub>2</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, PO<sub>4</sub><sup>-3</sup> shows the possibility of their occurrence in a wider range of concentrations. While this fact is less pronounced in parameters such as NO<sub>3</sub><sup>-</sup>, salinity and very little in the parameters pH, DO, EC, T and TDS.

**Figure 2.** The probability of distribution of the values of the studied parameters along the stations.

Correlation analysis was carried out to distinguish the parameters with similar behaviors in the water body. The results of the correlation analysis are shown in Table 2.

As can be seen from the table, pH shows a high correlation with TDS, which is related to the presence of Ca<sup>+2</sup> and Mg<sup>+2</sup> metal ions as well as CO<sub>3</sub><sup>-</sup> and HCO<sub>3</sub><sup>-</sup> anions, which are the result of the action of river water with limestone rocks, which are the main part of the mineralogical composition of the basin watershed.

Regarding the temperature parameter, a strong correlation can be seen with EC and salinity, but also with ion concentrations, since temperature affects their solubility.

Dissolved oxygen (DO) refers to the amount of oxygen gas present in water and is essential for aquatic life. All types of life in water, microorganisms, algae, fish, require oxygen for the development of their vital activity. There is a negative correlation with temperature, since the increase in temperature affects the amount of DO. Also, have a strong negative correlation with NO<sub>2</sub><sup>-</sup> ions, which consume DO as a result of their oxidation to NO<sub>3</sub><sup>-</sup>. There is also a negative correlation with NH<sub>4</sub><sup>+</sup> and PO<sub>4</sub><sup>-3</sup> ions, which are related to the processes of decomposition of biological materials and sewage discharges.

The strong correlation of these four parameters  $\text{NH}_4^+$   $\text{PO}_4^{3-}$   $\text{NO}_2^-$   $\text{NO}_3^-$  shows that their source is the same and is related to urban discharges or livestock farms in the waters of the Shkumbin River.

**Table 2.** Pearson correlation coefficient between: pH, Temp, EC, DO, TDS,  $\text{NO}_2^-$ ,  $\text{NO}_3^-$ ,  $\text{NH}_4^+$ ,  $\text{PO}_4^{3-}$ , Salinity.

	pH	Temp	EC	DO	TDS	$\text{NO}_2^-$	$\text{NO}_3^-$	$\text{NH}_4^+$	$\text{PO}_4^{3-}$
Temp	-0.301								
EC	-0.087	0.715							
DO	-0.238	-0.684	-0.415						
TDS	0.823	-0.109	-0.215	-0.493					
$\text{NO}_2^-$	0.044	0.538	0.504	-0.702	0.002				
$\text{NO}_3^-$	-0.107	0.505	0.417	-0.603	-0.156	0.910			
$\text{NH}_4^+$	-0.174	0.525	0.545	-0.382	-0.337	0.893	0.835		
$\text{PO}_4^{3-}$	0.081	0.486	0.513	-0.461	-0.122	0.906	0.803	0.963

$\text{PO}_4^{3-}$	$\text{NO}_2^-$	8	0.906	(0.556, 0.983)	0.002
$\text{NH}_4^+$	$\text{NO}_3^-$	8	0.835	(0.317, 0.969)	0.010
$\text{PO}_4^{3-}$	$\text{NO}_3^-$	8	0.803	(0.227, 0.963)	0.016
$\text{PO}_4^{3-}$	$\text{NH}_4^+$	8	0.963	(0.802, 0.993)	0.000

Fig. 3 shows the correlogram of the measured parameters, where it is clearly shown how the parameters correlate between them.

Table 3 shows the pairs of parameters that have a high negative or positive correlation (for values of  $P < 0.05$ ). This can be found in the correlogram, bearing in mind that pairs of parameters with high negative correlation are presented in strong blue color, while pairs of parameters with high positive correlation are presented without color (parameter pair Salinity, EC). Intermediate correlations based on level are shown in corresponding colors.

Figure 3. Correlogram of pH, Temp, EC, DO, TDS, NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, PO<sub>4</sub><sup>-3</sup>, Salinity

### Multivariable analysis (Cluster Analysis)

Through the computer program Minitab (Cluster method of data grouping) the dendograms of grouping of parameters based on the correlations between them were studied (Fig 4).

### Cluster Analysis of Variables: pH, Temp, EC, DO, TDS, NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, PO<sub>4</sub><sup>-3</sup>, Salinity

Final Partition

- Cluster 1      pH TDS
- Cluster 2      Temp EC NO<sub>2</sub><sup>-</sup> NO<sub>3</sub><sup>-</sup> NH<sub>4</sub><sup>+</sup> PO<sub>4</sub><sup>-3</sup> Salinity
- Cluster 3      DO

From the dendogram it can be seen that the parameters have similar values according to the stations forming the dendogram with 9 groups. In the first group, the parameters EC and salinity present high similarity of values between stations (similarity about 99%) which have 84% similarity with temperature. All three of these parameters influence each other, forming a set of parameters. EC is related to both temperature and salinity. High salinity values at station 8 have led to an increase in EC values. This happened because station 8 is located at the mouth of the river Shkumbin and the salinity of the sea water has an influence. Regarding the temperature, temperature fluctuations in the stations have led to EC fluctuations.

The second group of parameters consists of 2 subgroups and is related to the parameters NO<sub>2</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>, which present 95% similarity and the parameters NH<sub>4</sub>, PO<sub>4</sub>, which have 98% similarity. These two subgroups have a distribution similarity according to the stations of about 91%, forming a special group.

These two groups with 70% similarity to each other, form the main part of the dendrogram, which has a small similarity (about 33%) with the third group of parameters pH, TDS.

pH and TDS have similar values in stations around 84.9%, which means that TDS values have an impact on pH values. The first two groups and the third group of parameters form the large group where the similarity of the parameter values in the stations is about 33%

DO in the dendrogram is presented as a single group since the values of DO are not similar to those of other parameters, the similarity in this case is 14.9%.

Figure 4. The dendrogram of cluster analysis of variables.

In order to understand the relationship between the parameters in different stations and to evaluate the sources of change in these parameters, a Cluster Analysis of Observations was carried out. As can be seen from the dendrogram in Fig. 5, the stations, based on the parameter values, are divided into seven groups, which consist of two large groups, one with 5 stations and the other with 3 stations.

In the large group, with 5 stations, we distinguish 4 sub-groups. Stations 5 and 6 form a group with a similarity level of 78%, which are connected to station 7, which represents a single group, with a similarity level of 59.7%. All these stations belong to the field area and the contributors to the parameter values are the anthropogenic ones related to urban and agricultural and livestock activity. The discharges of untreated water from the villages and the use of pesticides, chemical fertilizers and the discharges of livestock farms, make the parameters in stations 5 and 6 not differ much from each other, while the similarity is the lowest in station 7, expressing an impact with lower anthropogenic, as the area is hilly and less populated.

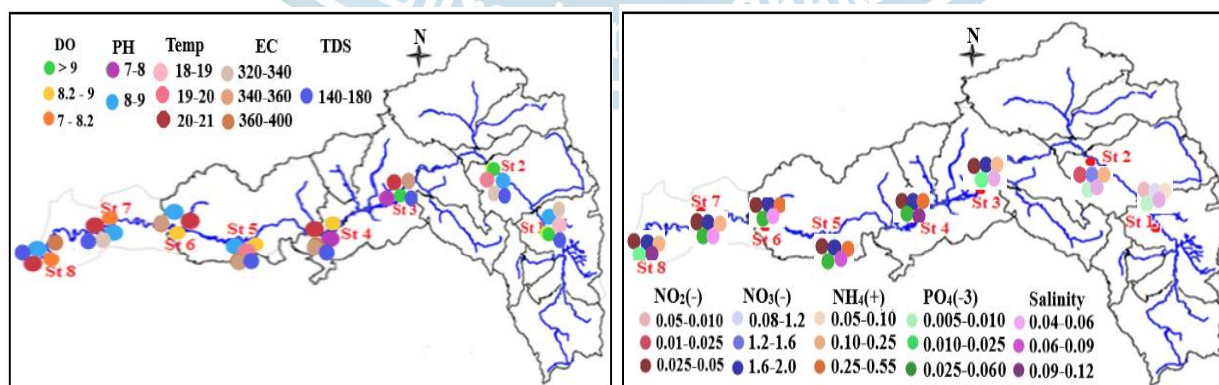

**Figure 5.** Dendrogram of similarity between monitoring stations.

Station 8 is presented alone, and the similarity with the previous stations drops to 44.4%, due to the salinization of the river water from the sea, since this station is located in the Shkumbin river delta.

Station 4 is presented as a single group, and has about 36% similarity with stations 5,6,7,8. This station expresses the anthropogenic effect on the river water related to urban activity. The discharge of sewage from the city of Elbasan, untreated in advance, into the waters of the Shkumbin River presents increased values of nutrients and EC and a decrease in DO.

Regarding the other group of stations (stations 1, 2, 3.), we can say that station 1, being far from residential centers and in an area with traditional agriculture, appears clean, therefore it forms a special group in the dendrogram. While stations 2 and 3, which have 69.8% similarity in the values of their parameters, are located after the town of Librazhdi, which is a small town and has a small effect on river pollution. But in these stations, erosion plays a role, since the river in these stations comes after a dislevelment of about 400 m with the first station and is erosive. These three stations form a common group with 45% similarity with the first station.

A presentation of the values of the physico-chemical parameters according to the stations is presented in figure 6

**Figure 6.** Values of physico-chemical parameters according to stations

## CONCLUSION

From the evaluation of the physico-chemical parameters and their comparison with the values recommended by WHO, we see that the physico-chemical parameters of the Shkumbin river water are within the recommended values. Some parameters are within the limit values, especially in station 4, which is related to the urban discharges of the city of Elbasan or discharges from livestock farms. Therefore, the establishment of a plant for the treatment of the city's sewage, as well as the control of the waste discharge of livestock farms, would help to eliminate these potential pollutants of the river waters.

#### Abstract

After death, the tooth is the most remaining tissue and an important sample for forensic science investigation. It is covered by the enamel and dentine layers, which contain a variety of chemical compounds. Nuclear magnetic resonance spectrometry is an instrument used for determining targeted and non-targeted metabolomics profiles. The purpose of this study was to identify biomolecules contained in human dentine using <sup>1</sup>H-NMR-based metabolomics. Dentine samples were collected from the second molar. The dentine powder was hydrolyzed at 100°C for 24 hours under acid condition. The solution was used for determining non-targeted metabolites by <sup>1</sup>H-NMR spectrophotometry. A total of one hundred and one chemical compounds were found in dentine, including organic acids, nucleic acids, fatty acyls, organoheterocyclic compounds, carbohydrates, organic nitrogen compounds, organic oxygen compounds, benzenoids, polyketides, alkaloids and lipids and lipid-like molecules. The levels of *L-N*-(3-carboxypropyl) glutamine, *N*-methyl-*L*-glutamic acid, citrulline, aminoacetone, 1-Methylguanine, glycine, dermatan sulfate, gamma-glutamylcysteine, *N*-acetylserine, ethyl glucuronide, creatinine, phosphohydroxypyruvic acid, phosphocreatine, mevalonic acid and *L*-pipecolic acid significantly decreased in males compared to females ( $p < 0.01$ ). Interestingly, this <sup>1</sup>H-NMR-based metabolomics technique utilizes a small amount of samples for chemical identification and could potentially be used for sex identification through machine learning models in the future.

**Keyword:** human dentine, <sup>1</sup>H-NMR, forensic science, biomolecule, Non-targeted Metabolomics

#### 1. INTRODUCTION

Human dentine is a white layer and contained with solid substances as the main tooth. Teeth are the hardest organ in the human body and difficult to decompose from charred burning and bury a corpse. Chemical components in dentine both organic and inorganic compounds were elucidated. Enamel contains inorganic matrix (96%, w/w), the protein (90% amelogenin), collagen, lipids, and water (4%, w/w). Dentine is the next part of the tooth enamel. The composition of dentine is similar to the bone, combining with 70% (w/w) of inorganic matters, 20% of organic matters, and 10% of water.

Chemical compounds have been investigated and utilized for many forensic science studies. In forensic odontology, tooth have been investigated for specific and individual characteristics in each person including for age and gender. Chromatography techniques have been identified for D and L-aspartic acid. For chemical identification by chromatogram technique, there are many steps for sample preparation. Easy step for sample preparation, rapid identification and highly sensitivity are need available.

Nuclear magnetic resonance spectroscopy (NMR) was first discovered in 1940. NMR has been widely used in physics and chemistry identification. At present, NMR technique is identified for metabolomics in human samples, including blood, serum, plasma, saliva, urine, and feces. The results have been used for prediction and diagnosis many diseases including heart diseases, diabetes and cancer.

The purpose of this study was to identify biomolecules contained in human dentine by <sup>1</sup>H-NMR 500 MHz. The chemical composition and the 1H-NMR technique can be applied in forensic science especially for gender and age identifications. Moreover, the cause of death, diseases, and toxic substances will be identified and might be linked to underlying disease in further.

## 2. MATERIALS AND METHODS

### 2.1 Chemicals

Hydrochloric acid (HCl) was obtained from Merck (Darmstadt, Germany). Deuterium oxide (D<sub>2</sub>O), trimethylsilyl propanoic acid (TSP) were obtained from Sigma-Aldrich (Ontario, Canada).

### 2.2 Dentine sample collection

Two hundred samples of non-carious permanent second molar (100 males and 100 females) age ranged 21 to 85 years old. The teeth samples were obtained from Department of Forensic Medicine, Faculty of Medicine, Chiang Mai University, Thailand. This research was approved by the Ethics Committee of Faculty of Medicine, Chiang Mai University (FOR-2565-09049). The teeth samples were cleaned with 0.9% normal saline solution and distilled water to eliminate blood remaining according the method of Manuela et al. The dried samples were stored at -20 °C until analysis.

### 2.3 Dentine preparation

Dentine samples were isolated by transverse section (1 mm) by Isomet 1000 using a low-speed cross-sectional saw and the enamel surface was subsequently removed by Airtor handpiece, brand NSK model PANA-MAX. Both preparing steps were under cooling water condition to avoid the heat.

### 2.4 <sup>1</sup>H-NMR conditions

Dentine samples were firstly pulverized by a freezing mill (SPEX CertiPrep - 6750 Freezer/Mill) for 15 min. Fifty grams of the dentine powder was digested with 50 mg of 0.6 M HCl at 100 °C for 24 hrs. The digested solution was lyophilized. 0.1 M of TSP in D<sub>2</sub>O was added into the sample tube and then the mixed solution was transferred into NMR tube. Record the proton NMR spectrum was acquired at 27 °C on a Bruker AVANCE 500 MHz (Bruker, Bremen, Germany) with Carr-Purcell-Meiboom-Gill (CPMG, -RD-90°-(t-180°-t) n-acquire) using water-suppression pre-saturation pulse sequence. A 90° pulse with a 16 number of signal averaging (NSA) was applied. The baseline and phase correction were carefully adjusted by Bruker TopSpin versions 4.0.7 software.

### 2.5 Peak Assignment and Untargeted Metabolite Identification

Identification of each biomolecule was determined by using The Human Metabolome Data Base (HMDB) and previous published paper [David et al., 2013]. Acquisition of peak, *J* couplings joint value were analyzed by using Bruker TopSpin versions 4.0.7 software.

**Table 1 shows the amounts of the top 101 chemicals and the variety of chemical compounds present in human dentin samples.**

Position	Chemical compounds	HMDB ID	Amount (%)
1	5-hydroxyindoleacetic acid	0000763	0.04

## RESULTS and DISCUSSION

In this study, human dentine samples obtained from Department of Forensic Medicine Chiang Mai University. The samples were hydrolyzed with hydrochloric acid to obtain free molecules. One hundred and one chemical compounds found in dentine samples and the results are shown in Table 1. The NMR chromatogram is shown in Figures 1. Chemical compounds including organic acids, nucleic acids, fatty acyls, organoheterocyclic compounds, carbohydrates, organic nitrogen compounds, organic oxygen compounds, benzenoids, polyketides, alkaloids and lipids and lipid-like molecules, and metabolites ethanol were found in human dentine. 5-hydroxy indole acetic acid (5-HIAA), 5-hydroxytryptopol (5-HTOL) and Ethyl glucuronide which are ethanol's metabolites could be detected and be indicate the deceased exposure to alcoholic beverages.

**Fig.3** PCA and PLS-DA analysis of chemical in human dentine expression between the groups. PCA score plots (A) and PLS-DA score plots (B) of chemicals in male and female dentine samples data.

The  $^1\text{H-NMR}$  is a popular technique for non-targeted metabolomic screening in various biological samples, including blood, urine, saliva and feces. This study represent the first research conducted in Thailand for non-targeted metabolites analysis in dentine performing by  $^1\text{H-NMR}$ . Specific central peaks were identified and mapped for each chemical by Human Metabolome Data Base (HMDB).

In Figure 2, volcano plot are presented, depicting different chemical compounds compared between male and female samples which the x-axis being log fold change and the y being  $-\log_{10}(\text{p-value})$  and  $\log_{2}\text{FC} > 1.2$ ,  $-\log_{10}(\text{p-value}) > 1.2$  ( $< 0.05$ ). A principal component analysis (PCA) and principle partial least square discrimination analysis (PLS-DA) plot demonstrated that certain chemical compounds could be exactly separated male and female.

Our results revealed that betaine, *L-N*-(3-carboxypropyl)glutamine, *N*-methyl-*L*-glutamic acid, Citrulline, Aminoacetone, 1-Methylguanine, Glycine, Dermatan sulfate, Gamma-glutamylcysteine, *N*-acetylserine, Ethyl glucuronide, Creatinine, Phosphohydroxypyruvic acid, Phosphocreatine, Mevalonic acid, *L*-pipecolic acid, Carnosine, Glycyl-aspartate, 2-Amino adipic acid were significantly higher concentration in male more than female samples ( $p < 0.01$ ). But, Oxoglutaric acid, *L*-isoleucine, Glycolic acid, 7-methyladenine, 3-Sulfinioalanine, *L*-Norleucine, 5-hydroxyindoleacetic acid, 2,3,4,5-tetrahydro-2, pyridinecarboxylic acid, 5-Hydroxytryptophol, *L*-alloisoleucine, Homocysteine thiolactone, *L*-alanine, Betaine, *L*-aspartyl-4-phosphate, Guanosine, Cis-4-hydroxy-D-proline, 5-methylcytosine, *L*-asparagine, *L*-homoserine, Norophthalmic acid significantly increased in female more than male ( $p < 0.01$ ). These compounds could be applied for sex investigation in Forensic Science. Particularly in the identification of anonymous skull or tooth fragments by  $^1\text{H-NMR}$  could be applied.

## CONCLUSION

This experiment demonstrated that  $^1\text{H-NMR}$  spectroscopy technique can identify 101 chemical compounds in human dentine samples. They categorized into organic acids, nucleic acids, fatty acyls, organoheterocyclic compounds, carbohydrates, organic nitrogen compounds, organic oxygen compounds, benzenoids, polyketides, alkaloids and lipids and lipid-like molecules. For application, *L-N*-(3-carboxypropyl)glutamine, *N*-methyl-*L*-glutamic acid, citrulline, aminoacetone, 1-methylguanine, glycine, dermatan sulfate, gamma-glutamylcysteine, *N*-acetylserine, ethyl glucuronide, creatinine, phosphohydroxypyruvic acid, phosphocreatine, mevalonic acid, *L*-pipecolic acid, carnosine, glycyl-aspartate, 2-amino adipic acid categorized male and female. Another biomolecules would be more identified and applied for forensic cases further.

## ACKNOWLEDGEMENTS

We grateful thanks Dr. Wirintra Watcharanone, Dr. Kanjana Inthongf, Dr. Atchara Pothikunapatg, Dr. Preeyajak Chinwaraphath for collecting the teeth samples.

#### Abstract

Following the discovery of cis-platin, the field of medicinal chemistry experienced an explosion in interest to organometallic compounds. The researchers suggest that the discovery of the potential antiangiogenic effects associated with anticancer activities will provide significant advancements in cancer therapy. Palladium complexes have garnered significant attention in the field of cancer research due to their resemblance in chemical and electrical properties to platinum compounds. Moreover, the lipophilic nature of palladium complexes has been found to enhance their antiangiogenic and anticancer properties. Benzimidazole derivatives are a class of chemicals that has garnered significant attention within the field of medicinal chemistry. The bioactivity of benzimidazole-based compounds arises from their structural resemblance to DNA or enzymes. On the contrary, the presence of many donor atoms renders phosphine-type compounds more appealing in the field of organometallic chemistry. The efficacy of phosphines in inhibiting cancer growth has been extensively demonstrated in numerous academic investigations. The objective of this study is to synthesize and describe novel complexes consisting of palladium, phosphine, and benzimidazole. The antioxidant capabilities of these complexes will be evaluated by using *in vitro* ABTS cation decolorization assay, while their antiangiogenic activities will be assessed through *in vivo* chorioallantoic membrane (CAM) method. All of the complexes showed strong antioxidant and antiangiogenic activity.

**Keywords:** Antiangiogenic, Anticancer, Antioxidant, Benzimidazole, Phosphine, Palladium.

#### INTRODUCTION

The potential of palladium complexes as anticancer drugs is substantiated by the resemblances observed between the metal complexes of platinum (II) and palladium (II) molecules, as reported by Miklášová et al. (2009). Platinum-based chemotherapeutic agents have played a crucial role within the realm of metal-based anticancer treatments. According to several studies, it has been found that palladium derivatives possess a significant cytotoxic impact, which can be compared to that of well-established platinum-based drugs like cisplatin, carboplatin, and oxaliplatin. Furthermore, these derivatives have been observed to cause fewer adverse effects compared to other heavy metal compounds used in anticancer therapy (Divsalar et al., 2007; Miklášová et al., 2009). According to a study conducted by Saygideğer Demir et al. in 2014, it was shown that phosphine metal complexes have inhibitory effects on antioxidant enzymes and cytotoxic effects on lung and leukemia cell lines. Previous studies have reported the *in vitro* anticancer properties and *in vivo* angiogenic effects of several gold phosphine metal complexes (Bagowski et al., 2009; Reddy et al., 2018). The benzimidazole ring system is commonly found in numerous bioactive heterocyclic compounds, owing to its diverse range of biological and medicinal applications. Benzoimidazoles have garnered significant attention from medicinal and synthetic organic chemists due to their diverse range of biological actions. This group of heterocyclic molecules has been extensively studied and is known to possess various properties, including antidiabetic, anticancer, hormone antagonist, antiviral, anti-HIV, anthelmintic, antiprotozoal, antimycobacterial, antihypertensive, anti-inflammatory, analgesic, anxiolytic, coagulant, anticoagulant, antioxidant, antidiabetic, and antiallergic properties (Rashedy and Aboul-Enein, 2013; Shrivastava et al., 2017).

According to the molecules inherent biological characteristics, the present investigation involved the synthesis of two novel complexes including palladium, phosphine, and benzimidazole. The structural characteristics of these complexes were determined through the application of diverse spectroscopic methodologies. The objective of this study was to assess the antioxidant effects of these compounds *in vitro* using metal chelating, reducing power assessment, ABTS cation decolorization, and *in vivo* antiangiogenic activities utilizing the chorioallantoic membrane (CAM) method, which has not been previously explored.

## MATERIALS AND METHODS

### Synthesis of benzimidazole derivatives

During the synthesis step, the reaction was conducted by combining benzimidazole with benzyl bromide, and separately, 4-bromobenzyl bromide and 4-methylbenzyl bromide. This reaction took place in a dimethyl sulfoxide solvent under reflux conditions in a basic environment, utilizing potassium hydroxide. Following the completion of the reaction, a series of separation and purification techniques, including extraction, column chromatography, and thin layer chromatography, were employed to obtain the desired product. As a result, three distinct benzimidazole derivatives were obtained.

### Synthesis of new palladium complexes

The experiment involved the addition of triphenylphosphine, tri-*p*-tolylphosphine, or tris (4-methoxyphenyl) phosphine chemical dissolved in acetonitrile dropwise to a solution of palladium chloride in acetonitrile. Following an hour-long stirring period at a temperature of 40°C using a magnetic hot mixer, the mixture was dissolved in acetonitrile. Subsequently, the produced benzimidazole compounds were added dropwise. Following a 12-hour period of stirring, the entirety of the solution was subjected to evaporation through the process of filtration. Consequently, two distinct palladium complexes were obtained.

### Characterization of synthesized molecules

X-Ray Single Crystal Spectroscopy, Nuclear Magnetic Resonance Spectroscopy (NMR), HR-Mass Spectroscopy, Infrared Spectroscopy or Fourier transform infrared spectroscopy (FT-IR) were performed using Elemental Analysis methods.

### *In vitro* ABTS decolorization assay

The decolorization assay for ABTS and its reducing power were assessed using the methodology outlined by Re et al. (1999). ABTS was dissolved in water to achieve a concentration of 7 mM. The generation of ABTS radical cation was achieved by combining ABTS stock solution with a final concentration of 2.45 mM potassium persulfate. The resulting combination was then allowed to incubate in darkness at room temperature for a duration of 12-16 hours prior to utilization. The reagent utilized in this work necessitates fresh preparation before to each experiment. It was diluted with ethanol to achieve an absorbance reading of 0.700 ( $\pm$  0.02) at a wavelength of 734 nm. This reagent was subsequently employed in the assessment of antioxidant activity. In the experimental procedure, a volume of 1 mL of reagent solution was introduced to a volume of 10  $\mu$ L of sample solution, which had a concentration of 0.5 mg/mL. The resulting mixture was allowed to incubate for a duration of 5 minutes, after which the absorbance of the solution was determined at a wavelength of 734 nm. In the research conducted by Re et al. (1999), ethanol was employed as a blind, while a trolox solution with a concentration of 0.5 mg/mL was utilized as a positive control. The calculation of radical scavenging activity (RSA) involved determining the percentage inhibition of ABTS radical reduction using the following formula: "% ABTS scavenging = [(A control - A sample) / A control]  $\times$  100".

### *In vivo* angiogenic activity (CAM assay)

#### Preparation of test samples

Benzimidazole derivatives and new palladium complexes, along with a positive control of ( $\pm$ )-Thalidomide and a negative control of SDS, were dissolved in a 2.5% (w/v) agarose solution. The chick chorioallantoic membrane was treated with 10 mL of these solutions, which were prepared and put onto circular stainless-steel supports with a diameter of 5 mm. The solutions were cooled to room temperature to solidify before being applied onto the CAM.

### *In vivo* chick embryo chorioallantoic membrane (CAM) assay

The present study conducted an *in vivo* CAM analysis, using the methodology outlined in previous publications by Gurel-Gurevin et al. (2018), Ünver et al. (2022), and Yurtdaş-Kırımlioğlu et al. (2022a, 2022b).

The fertilized hen eggs had a 72-hour incubation period at a temperature of 36.5°C, accompanied by a relative humidity of 80%. Subsequently, the eggs were placed in a horizontal orientation and subjected to many rotations. After the eggs were opened on the side opposite the snub, a volume of 10-15 mL of albumin was extracted. The eggs were incised using a scalpel at a position two-thirds of their height, measured from the pointed end. Subsequently, the shells were extracted using forceps. The cavity was sealed using stretch film, and the eggs were placed in an incubator set at a temperature of 36.5 °C and a relative humidity of 80% for an additional duration of 72 hours. The CAM was prepared by placing one pellet per egg, with each pellet having a diameter of roughly 2 cm. The hole in the egg shell was then sealed once more with stretch film. The eggs were seen after a duration of twenty-four hours utilizing a stereomicroscope. Each test condition employed a range of 10 to 15 eggs. The examination of each sample was conducted three times, with each examination being performed in duplicate. The anti-angiogenic effects were evaluated using a grading system, as shown in Table I. The subsequent equation was employed to get the anti-angiogenic scores: The mean score is determined by the formula  $[\text{Number of eggs (score >1)} + 2 \times \text{Number of eggs (score >0.75-1)}] / (\text{total number of eggs scored})$  (Gurel-Gurevin et al., 2018; Ikitimur-Armutak et al., 2017; Kiyani et al., 2014). In order to provide positive and negative controls, the compounds Thalidomide and sodium dodecylsulfate (SDS) were used in the study. These controls were tested at a concentration of 50 mg/pellet. In order to conduct blank tests, solidified agarose-solution pellets (2.5%, w/v) were utilized for the treatment of CAMs. Each experiment was replicated three times.

**Table 1.** Score system of anti-angiogenic effect

Scale	Anti-angiogenic effect	Effects observed on CAM after treatment
<0.5	Inactive	No change in embryo
0.5 - 0.75	Weak	No capillary free area
0.75 - 1	Strong	Small capillary free area
>1	Very strong	Capillary free area around the pellet

## RESULTS and DISCUSSION

### Characterizations of complexes

*Complex 1*; Yellow solid (Yield=49%), FT-IR (KBr) cm<sup>-1</sup>: 3082-2837, 1592, 1498, 1290, 1251, 1178, 1099, 1021, 825, 799, 752, 727, 537. Calc.: C<sub>32</sub>H<sub>26</sub>BrCl<sub>2</sub>N<sub>2</sub>PPd: C, 52.88; H, 3.61; N, 3.85; Result: C, 52.75; H, 3.42; N, 3.83.

*Complex 2*; Yellow solid (Yield=49%), FT-IR (KBr) cm<sup>-1</sup>: 3104-2837, 1592, 1520, 1489, 1463, 1390, 1261, 1188, 752. Calc.: C<sub>35</sub>H<sub>32</sub>BrCl<sub>2</sub>N<sub>2</sub>PPd: C, 54.68; H, 4.20; N, 3.64; Found: C, 54.18; H, 4.35; N, 3.16.

### *In vitro* ABTS decolorization assay

Antioxidant activity results of Pd complexes 1 and 2 by ABTS cation decolorization/inhibition assay are given in Table 2. The highest 68.56 % inhibition activity was determined with complex 2. Both of complexes showed strong antioxidant activity when compared with control groups.

**Table 2.** ABTS % inhibition rates

Pd complexes/Control groups	% Inhibition
Complex 1	49.79 ± 0.1
Complex 2	68.56 ± 5.01
BHT	43.55 ± 1.3
Ascorbic Acid	96.56 ± 0.5

### ***In vivo* angiogenic activity (CAM assay)**

Antiangiogenic effect scores regarding the results of antiangiogenic activity of Pd complexes 1 and 2 by *in vivo* CAM method are given in Table 3. When the results are evaluated according to the score table both of complexes showed strong antiangiogenic activity.

**Table 3.** Antiangiogenic activity scores

Pd complexes	Concentration (mg/pellet)	Average score	Anti-angiogenic effect	Irritation/Tox (%)
Complex 1	50	0.9 ± 0.2	Strong	-
Complex 2	50	0.85 ± 0.2	Strong	-
(±)-Thalidomide	50	0.9 ± 0.1	Strong	-
SDS	50	-	-	84.3 ± 0.02
Agar (blank)	% 2.5, w/v	-	Inactive	-

### **CONCLUSION**

The current state of literature lacks research examining the antioxidant and antiangiogenic properties of Pd, phosphine, and benzimidazole complexes produced within the scope of this project. Hence, given that the investigation focused on evaluating the antioxidant and antiangiogenic properties of palladium complexes synthesized in this study, it is possible to consider that these synthesized complexes hold potential as a novel therapeutic agent in the development of drugs aimed at inhibiting angiogenesis induced by oxidative stress.

### **ACKNOWLEDGEMENTS**

#### Abstract

Antimicrobial agents are used to reduce clinical infections and production losses caused by microorganisms in poultry industry. Backyard poultry flocks have become increasingly popular and little is known about the main cause of bacterial infections in these populations. In this case study, were examined 30 different backyards poultry flocks in Elbasan district, Albania for the presence of *Pseudomonas aeruginosa* and *Escherichia coli* in sudden found dead poultry carcasses and their visceral organs respectively. These gram-negative agents were tested simultaneously against 5 antibiotics: Ampicillin AMP, Amoxicillin AMX, Ciprofloxacin CIP, Enrofloxacin ENR, Gentamicin GEN and Polymyxin B POLYB. In total, n=120 samples (carcasses and viscera) were tested, from which 32 strains of *P. aeruginosa* (26, 67%) and 44 of *E. coli* (36, 66%), were isolated.

The laboratory findings emphasised the presence of both bacteria in 30% of the assayed flocks. Moreover, all of the tested isolates were resistant towards up to three of the tested antibiotics. Relevant data of high resistance against Ciprofloxacin CIP (53, 94% of the n=76 tested isolates) and Polymyxin B POLYB (63, 15% of the n=76 tested isolates) were reported. These data reveal relative risk of spread and development of antimicrobial resistance in zoonotic agents, which can lead to therapy failures, economic losses and concerns of veterinary public health.

#### INTRODUCTION

The inappropriate use of a wide range of antimicrobials for prophylactic, therapeutic, and growth-promotion purposes over a prolonged period of time contributes to the failure in poultry management and biosecurity, promoting the selective pressure of antimicrobial-resistant microorganisms and the emergence and spread of AMR strains. Antimicrobial resistance (AMR) is a growing concern in both commercial poultry farming and backyard poultry. The use of antimicrobials as growth promoters in small-scale chicken farming has been identified as a contributing factor to the development of antimicrobial resistance in poultry (Hedman et al., 2020). A pilot study (Alcaine et al., 2015) conducted in Albanian poultry farms found that bacterial isolates had much higher levels of antibiotic resistance compared to EU countries. Another study found that avian pathogenic *Escherichia coli* resistance patterns in Albania were extremely high against Neomycin, Doxycycline, Trimethoprim-Sulfamethoxazole, and other antibiotics (Shtylla et al., 2023). In backyard poultry, the use of antibiotics is generally lower than in commercial poultry farming, but AMR can still be a concern. Backyard poultry, which are generally raised without routine antimicrobial therapy, can function as both a regular source of marginal income and a potential source of AMR (Hedman et al., 2020). Backyard poultry may be more susceptible to disease due to poor biosecurity measures, which can lead to the overuse of

antibiotics (Nhung et al., 2017). Additionally, the close proximity of backyard poultry to humans can increase the risk of transmission of antibiotic-resistant bacteria (Hedman and Zhang, 2020). In Albania backyard poultry flocks have become increasingly popular and little is known about the main cause of bacterial infections in these populations or the antimicrobial resistance of these pathogens. This study is focused in 30 different backyards poultry flocks in Elbasan district, Albania for the presence of *Pseudomonas aeruginosa* and *Escherichia coli*. After the isolation of these two agents, the possible level of antimicrobial resistance was examined to better understand the present risk of AMR.

## MATERIALS AND METHODS

In this case study, were examined 30 different backyards poultry flocks in Elbasan district, Albania for the presence of *Pseudomonas aeruginosa* and *Escherichia coli* in sudden found dead poultry carcasses and their visceral organs respectively. During the period of time March-April 2023, a total of 120 samples were collected and the laboratory analysis were carried out in the Faculty of Veterinary Medicine of Tirana.

The samples (visceral organs), were inoculated into the non-selective pre-enrichment medium, Buffered-Peptone Water and incubated at 37 °C for 24 h. Cultures obtained were plated onto MacConkey agar for the detection of *E. coli* and Cetrimide agar for the detection of *P. aeruginosa*, and incubated at 37 °C for 24 h. Suspected *E. coli* colonies were streaked onto Tryptone Bile X-Glucuronide and incubated at 42 °C for 24 h. Finally, all isolates were biochemically identified by using API 20E system, whereas potential *Pseudomonas* spp. colonies were submitted to oxidase test and processed by biochemical identification by API 20 NE system.

All isolates were submitted to antimicrobial susceptibility testing using the disc diffusion method (Kirby-Bauer test) against 5 different antibiotics: Ampicillin (AMP), Amoxicillin (AMX), Ciprofloxacin (CIP), Enrofloxacin (ENR), Gentamicin (GEN) and Polymyxin B (POLYB).

## RESULTS and DISCUSSION

Overall 120 samples analysed, from 30 different poultry flocks, 76 (53,95%) of them resulted positive for *Escherichia coli* and *Pseudomonas aeruginosa*, from which 44 (36,66%) strains of *E.coli* and 32 (26,67%) strains of *P.aeruginosa* were isolated.

**Table 1.** Isolated strains of *E.coli* and *P.aeruginosa* from backyard poultry

Total No.of sample analysed	<i>E.coli</i> strains	<i>P.aeruginosa</i> strains
120	44 (36,66%)	32 (26,67%)

**Figure 1.** Isolated strains from 120 backyard poultry samples

Accordingly to the type of infection, all of the 44 *E. coli* strains were tested for their antibiotic-resistance performing antibiogram by disk diffusion method, Kirby Bauer 1966. The results presented in the table no. 2 evident high percentages of bacteria resistance against selected veterinary drug classes. Prominent results of antibiotic-resistance against Quinolones remain important in colibacillosis treatment.

**Figure 2.** Antibiotic resistance for *E. coli* isolated strains

*Pseudomona aeruginosa* isolates were also investigated towards antimicrobial resistance. Important and elevated levels of resistance encountered in tested isolates highlighted the presence of 18 resistant strains against Polymyxin B or 56, 25% of all of the tested *P. aeruginosa* isolates. Polymyxins are currently the last-resort antibiotics for the treatment of multidrug-resistant Gram-negative bacterial infections (Yang et al., 2023). Moreover, previous data for the human treatment of *P. aeruginosa* bacteremia have identified the efficacy of Polymyxin B in severe infections (Kvitko et al., 2011).

Figure 3. Antibiotic resistance of *P.aeruginosa* isolated strains

Nevertheless higher resistance percentages in *E.coli* isolated, sampled from clinically affected poultry and with evident colibacillosis lesions were presented, it is crucial to remark that similar antibiotic-resistance was detected in both bacteria, as shown in the figure no.4.

Figure 4. Resistance percentage of *E.coli* and *P. aeruginosa* strains

Disposal of animal wastes as a manure is another source of transmission of resistant pathogens from animal farms to the soil. This problem has been increased due to the concentrated animal feeding practices. As a result, resistant bacteria and antimicrobials residues accumulate in the soil and proliferate antibiotic resistance in soil inhabiting bacteria (Gosh and LaPara, 2007). It is important to note that both *Escherichia coli* and *Pseudomonas aeruginosa* can cause infections in poultry and can also be resistant to antibiotics (Varriale et al., 2020), (Nolan 2018). This study shows that backyard poultry are a potential source of these pathogens and were both isolated in a high percentage which highlights the need for further investigations.

## CONCLUSION

AMR in poultry is a complex issue that requires a multifaceted approach to address. Improved hygiene and sanitation, reduced use of antibiotics, and the use of non-conventional antimicrobial compounds are some strategies that can help reduce the prevalence of AMR in both commercial and backyard poultry farming. It is obvious that excessive use of antibiotics in poultry to increase the growth of broiler chicken is developing a serious sort of resistance in bacteria by production of antimicrobial resistance.

The conducted study in Elbasan district led to results similarities between different free-range poultry farms. Thus it can be concluded that the pattern of resistance in the surrounding area of a poultry farm is highly influenced by mutual geographical area and choice of antibiotics used inside the farm.

In conclusion, high levels of antimicrobial resistance in *Pseudomonas aeruginosa* and *Escherichia coli* strains found in backyard poultry is a concern that requires immediate attention. The use of antimicrobials as growth promoters in small-scale chicken farming is a contributing factor to the development of AMR in poultry. To address this issue, it is important to promote judicious antimicrobial use in the poultry industry and to develop alternative strategies for disease prevention and control. Preventive measures have to be adopted in order to minimize the spread of antibiotic-resistant bacteria, especially *P. aeruginosa* in farm environment and from poultry to humans.

#### **Abstract**

*Abies cilicica* (Ant. & Kotschy) Carr. subsp. *isaurica* Coode & Cullen is an endemic species belonging to the Pinaceae family, commonly known as 'Bozkır Göknaarı', distributed in the west of the Toros Mountains in Turkey. *A. cilicica* subsp. *isaurica* has antimicrobial, antiseptic, anti-inflammatory and antioxidant properties and is known to be used in the treatment of acne, ulcers, asthma and wound healing, bronchitis, stomach pain and digestive facilitator against various diseases. In this study, the phytochemical profile of *A. cilicica* subsp. *isaurica* leaf methanol extract was determined by HPLC system and within the scope of *in vitro* biological activities antimicrobial activity was investigated by microbroth dilution method, antioxidant activity by ABTS method and anti-inflammatory effect by COX-1, COX-2 enzyme inhibition method for the first time. The *A. cilicica* subsp. *isaurica* leaf methanol extract showed antimicrobial activity with the concentrations between 312,5-2500 µg/mL against Gram positive, Gram negative bacteria species and *Candida*. The leaf extract also exhibited high antioxidant and anti-inflammatory activity with 77.42% and 50.63% inhibition at the 200 µg/mL concentration.

**Keywords:** *Abies cilicica*, Phytochemical, Antimicrobial activity, Antioxidant activity, Anti-inflammatory activity.

#### **INTRODUCTION**

The genus *Abies*, belonging to the Pinaceae family, encompasses a total of 48 species and 78 taxa worldwide. In the specific context of Türkiye, there are 3 species and 5 taxa of *Abies* (Güner et al., 2012). Out of the taxa mentioned, two of them are considered endemic species. These species are classified as *Abies cilicica* subsp. *isaurica* Coode & Cullen Ir (lc) and *Abies nordmanniana* subsp. *equi-trojani* (ASC. & Sint. ex Boiss.) Coode & Cullen, falling under the LR (nt) category (Pulatoğlu et al., 2023). *Abies cilicica* (Ant. & Kotschy) Carr. subsp. *isaurica* Coode & Cullen is an endemic species commonly known as 'Bozkır Göknaarı', distributed in the west of the Toros Mountains in Türkiye (Yavaser et al., 2015). The resin derived from *Abies cilicica* has historically been employed for its medicinal properties, serving as an antiseptic, anti-inflammatory, antipyretic, antibacterial, and antiviral agent. In our country, it is known that the resin obtained from the cones of *A. cilicica* species is used externally as antiseptic and boil remedy as moxibustion or ointment (Baytop, 1999). In the treatment of gastrointestinal diseases, psoriasis, reflux, ulcers, asthma, bronchitis (Çakır, 2017) (Tumen et al., 2011) (Tumen et al., 2011), the resin contained in the cones of *A. cilicica* subsp. *isaurica* is used in the treatment of acne, ulcers, asthma and wound healing (Yeşilada et al., 1995) (Yavaser et al., 2015) (Çakır, 2017), against psoriasis, bronchitis, stomach pain and as a digestive facilitator (Çakır, 2017). It is known that tar is used as antiseptic, in the treatment of abscess, abdominal pain and as a digestive facilitator (Yavaser et al.,

2015). It has also been reported that its fruits (cones) are used as decoction in the treatment of vascular diseases (Yeşilada et al., 1995) (Tumen et al., 2011). Because of these properties, this study focused on determining the biochemical contents of *Abies cilicica* subsp. *isaurica* leaves methanol extract and examining the biological activities in the context of antimicrobial, antioxidant, anti-inflammatory properties.

## MATERIALS AND METHODS

### Preparation of Extract

The leaves of the endemic *A. cilicica* subsp. *isaurica* species were collected from Alanya (Antalya) and Fethiye (Muğla) in Antalya and Muğla regions in 2017 and identified by Forest Engineer Mahmut Tunahan. Methanolic extract of the leaves of *A. cilicica* subsp. *isaurica* were obtained by maceration with methanol at room temperature. The solvent was removed by using a rotary evaporator and dry extract were obtained.

### Liquid-Chromatographic Analyses

The methanolic extract was analysed by LC-MS/MS (Liquid Chromatography-Mass Spectrometry/ Mass Spectrometry) system to assess its phytochemical composition.

### *In vitro* Anti-inflammatory Activity Test by COX-1 and COX-2 Enzyme Inhibition Method

Purified COX-1 and COX-2 enzymes were used for *in vitro* determination of anti-inflammatory COX-1 and COX-2 inhibitory effect. The amount of PGE<sub>2</sub> was measured by EIA (Vazquez et al., 1997). The activity results were determined colorimetrically in Elisa microplate reader and given as % inhibition.

### Antimicrobial Activity Test

The Clinical and Laboratory Standards Institute's (CLSI) microbroth dilution susceptibility assay (CLSI 2012, 2002a) was used to test the antimicrobial activity of plant extract. *Escherichia coli* (ATCC 35218), *Bacillus subtilis* (NRRL B478), *Pseudomonas aeruginosa* (ATCC 27853) strains were subcultured overnight at 37 °C in Mueller Hinton Agar (MHA) and *Candida albicans* (ATCC 10231) in Sabouraud Dextrose Agar (SDA) at 30 °C. Overnight microorganism cultures were adjusted to 1 × 10<sup>8</sup> CFU/mL using McFarland 0.5 standard turbidity in sterile saline (0.85%) solution and homogenized by vortex. The plant extract was dissolved in methanol for the initial stock solution. The concentrations of plant extract was prepared by a two-fold serial dilution technique in 96-well microplate to 2500-4 µg/mL. After the dilution step, 100 µL of each microorganism culture were inoculated to the well plates and incubated at 37 °C, 24 h for bacteria and at 30 °C for 48 h for yeast. At the end of the incubation period, all wells were stained by adding 20 µL 0.01% resazurin solution to observe the color difference between dead and living cells (colors ranging from blue (green) to pink). Ketoconazole, ciprofloxacin and chloramphenicol were used as reference agents for antimicrobial activities against *C. albicans* and bacteria species. The experiment was repeated three times, and the results were averaged.

### Antioxidant Activity Test

The antioxidant activity of plant extract was determined by using ABTS (2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonic acid)) (Re et al., 1999) method. ABTS (7 mM) was dissolved in water with 2.45 mM potassium persulfate and the solution was kept in the dark room for 16 h. Standardized ABTS solution was prepared with ethanol to obtain 0.70±0.002 absorbances. Stock solutions of plant extract (200 µg/mL), ascorbic acid (100 µg/mL) and gallic acid (100 µg/mL) were prepared in ethanol. The ethanol was used as negative control and ascorbic acid (Vit C), gallic acid were used as a positive control. The radical scavenging activity (RSA) was calculated as the percentage inhibition of ABTS radical reduction as follows  
“%ABTScavenging = [(A<sub>control</sub> - A<sub>sample</sub>) / A<sub>control</sub>] × 100”

## RESULTS and DISCUSSION

### Liquid-Chromatographic Analyses

For LC-MS/MS analysis, Absciex 3200 MS/MS detector was used. Chromatographic separations were performed using Shimadzu 20A HPLC with an ODS 150 x 4.6 mm x 3  $\mu$ m column. The column oven temperature was set to 40 °C and the flow rate was set to 0.5 mL/min. Mobile phases were (A) Methanol: water: formic acid (10:89:1, v/v/v) and (B) Methanol: water: formic acid (89:10:1, v/v/v). The concentration of B was increased from 10% to 100% in 40 min. A mass range of 100-1000 amu was chosen for mass screening (EMS). The results were given in Table 1.

**Table 1.** Compounds identified in methanol extract

Rt	[M-H] <sup>-</sup>	MS/MS	Identification
3.5	191	173, 127	Quinic acid
9.4	163	119	Coumaric acid
14.0	431	385, 223, 205, 153	Rosaceous-like
16.2	315	299, 269, 255	Methylquercetin
17.0	433	343, 313	Naringenin-C-glucoside
18.0	577	456, 413, 311, 293	Apigenin-O-rhamnose-C-glucose
20.1	463	315, 300, 271	Methylquercetin rhamnoside
21.0	461	300, 271, 179, 151	Quercetin glucoside
22.8	345	301, 257, 179	Unknown
23.3	447	300	Quercetin rhamnoside
26.0	431	285, 255, 227	Luteolin/campferol rhamnoside
32.4	739	593, 453, 285	Kemferol/luteolin deoxyhexose derivative
37.0	723	577, 559, 437, 285	Kempferol/luteolin deoxyhexose derivative

### COX-1 and COX-2 Enzyme Inhibition Test

The anti-inflammatory activity of *A. cilicica* subsp. *isaurica* leaf methanol extract was determined by COX-1 and COX-2 Enzyme Inhibition Test and % inhibition rates were determined (Table 2.). The 50.63% inhibition activity was determined at the 200  $\mu$ g/mL concentration. When compared with the control group Selekoksisb, the result was satisfactory.

**Table 2.** COX-1 and COX-2 Enzyme % inhibition rates

Concentration	100 µg/mL	200 µg/mL
	<b>% Inhibition</b>	
<i>A. cilicica</i> subsp. <i>isaurica</i> leaf methanol extract	15.00	50.63
<b>Control group Selekoksib</b>	<b>90.54</b>	<b>91.83</b>

### Antimicrobial Activity Test

The MIC values of *A. cilicica* subsp. *isaurica* leaf methanol extract were given in Table 3. The minimum inhibitory concentrations of plant extract varied between 312,5-2500 µg/mL. According to the MIC values methanol extract of *A. cilicica* subsp. *isaurica* leaf exhibited poor antimicrobial activity against *Escherichia coli* and *Bacillus subtilis* with high concentrations. As a result, only the *Pseudomonas aeruginosa* is more sensitive than other bacteria species, similarly with *Candida albicans*.

**Table 3.** MIC values

	MIC µg/mL			
	<i>Escherichia coli</i>	<i>Bacillus subtilis</i>	<i>Pseudomonas aeruginosa</i>	<i>Candida albicans</i>
<i>A. cilicica</i> subsp. <i>isaurica</i> leaf methanol extract	2500	625	312,5	312,5
Ciprofloxacin	-	-	4	-
Ketoconazole	-	-	-	312,5
Chloramphenicol	8	4	-	

### Antioxidant Activity Test

The methanol extract of *A. cilicica* subsp. *isaurica* leaf exhibited high antioxidant activity compared with control groups of gallic and ascorbic acid (Table 4). The 77,42% inhibition activity was determined at the 200 µg/mL concentration.

**Table 4.** ABTS % inhibition rates

	<b>ABTS % inhibition</b>	<b>Concentrations</b>
<i>A. cilicica</i> subsp. <i>isaurica</i> leaf methanol extract	77,42	200 µg/mL
Gallic Acid	88,28	100 µg/mL
Ascorbic Acid	84,23	100 µg/mL

## CONCLUSION

In this study, the phytochemical composition of methanol extract prepared from the leaves of *A. cilicica* subsp. *isaurica* was investigated for the first time with HPLC system. In addition, the *in vitro* anti-inflammatory effect of the extract was examined for the first time using COX-1, COX-2 enzyme inhibition methods. The antimicrobial and antioxidant activities were also evaluated in this study. It is thought that the effects can be evaluated by *in vivo* animal experiments as a preliminary preparation for clinical studies.

## ACKNOWLEDGEMENTS

#### Abstract

In biomedical diagnostics, electrochemical cells are important tools. This study explains the application of electrochemical cells in biomedical diagnosis, focusing on the modulation of impedance information at different frequencies as a function of cell fluid content. The relationship between the sample's composition and the chamber's reaction dynamics with impedance at distinct frequencies is examined. Also, a novel, practical and low-cost chamber design is presented.

To explain the underlying principles governing the electrochemical cell's behavior, an electrical equivalent circuit model for the chamber is proposed. The chamber's ionic fluid content for different concentrations is monitored through impedance spectroscopy. This study showed that electrochemical impedance spectroscopy can be used as economic and efficient tool for biomedical diagnostics with implications for a wide range of applications in the field of healthcare and life sciences.

**Keywords:** Impedance spectroscopy, microfluidics, biosensor, diagnosis, electrochemical chamber

#### INTRODUCTION

##### Electrochemical Cell

A basic Electrochemical impedance measurement setup consist of chamber with two electrodes in an electrolyte solution. The impedance for different alternating current (AC) signal with a constant frequency is dependent on several factor due to the solution dynamics and reactions. These factors include ion migration, the presence of free electrons in the solution, and the system's capacitive response. Electrical impedance spectroscopy is the impedance value for various frequencies. (Lasia, 2014) The resistivity of the bulk solution, permittivity of the solution, geometric electrode placement, electrode-solution interface, electrochemical processes occurring on the electrode and electrolyses have an effect on the impedance value in the two electrode systems. (Grimnes et al., 2005)

The data obtained from the EIS system is usually an impedance data for a specific frequency. An electrical equivalent model of an electrochemical system allows for more thorough data analysis, which may provide information about the structure of the materials in the electrochemical cell and the reactions formed in it.

##### Electrical Equivalent Model of a Cell

The design of the system, such as geometric placement of the electrodes and resistivity and permittivity features of the solution, makes bulk resistance and the capacitance of the model simply definable.

There is a relationship between resistivity and the quantity and mobility of the unbound electrons in a substance. Additionally, based on an electrical field applied to the substance, there is a relationship between permittivity and polarization. If the elements in the solution are changed, the resistivity and permittivity of the solution vary.

Different types of geometric configurations of two electrode systems exist, which are forward looking electrodes, co-planar electrodes and interdigitated electrodes. To reveal particular characteristics of electrical information, alternative electrode configurations may be utilized.

According to the description of the electrical equivalent circuit model, the experimental data and the equivalent circuit data must fit. The constituent parts of the electrical equivalent circuit model of the electrochemical cell should be evaluated based on an analysis and comprehension of the physical and chemical characteristics of the electrochemical system. (Krause, 2007)

In the electrical field, ion migration based on electrode charges leads to a double layer of charge on the electrode's surface, separated by a thick dielectric. This structure is called double layer capacitance ( $C_{DL}$ ), which depends on frequency, and it is influenced by factors such as electrode potential, temperature, ion types, ionic concentrations, impurity adsorption, oxide layers, electrode roughness, electrode potential, and so on. (Luo, 2013 and Genry, 2017)

When surfaces are inhomogeneous, rough, or porous, which leads to observing frequency-dependent behaviour, since ideal capacitor model is suitable, constant phase element (CPE) is employed to model the actual double layer capacitance.  $\alpha$  means phase coefficient, which represents the behaviour of CPE. (Hong et al., 2005 and Córdoba et al., 2015)

The ratio of the applied voltage to the current resulting from the charge transfer is defined as the charge transfer resistance ( $R_{CT}$ ). The resulting current is influenced by the transferred ion concentration, potential formed during electrochemical reactions and reaction products. (Lvovich, 2012)

The impedance occurring because of the ion migration and diffusion in the diffusion layer stands for Warburg impedance ( $Z_W$ ). It is strongly influenced by the frequency of the applied voltage. Higher frequencies result in lower  $Z_W$  because of faster ion migration or vice versa for lower frequencies. (Lvovich, 2012)

**Figure 1.** Randles electrical equivalent circuit model for an electrode.  $R_{CT}$  is the charge transfer resistor,  $Z_W$  is Warburg impedance,  $C_{DL}$  is the double layer capacitance, and  $R_{sol}$  is bulk resistance.  $R_{CT}$  and  $C_{DL}$  are related to the electrode-electrolyte interface and the reactions in that area that include the linear, semi-infinite diffusion of electroactive particles between electrode and electrolyte.

The resistance of the bulk solution can be easily clarified for higher frequencies in Bode plots of Randles electrical equivalent circuit model. In Nyquist plot, the imaginary versus real components of the impedance value graph can be plotted for the Randles equivalent circuit model, and the resulting graph includes information about both phase and magnitude. Nyquist and Bode plots provide the best visualization and description of the Randles model. (Randviir and Banks, 2013)

Lower frequencies have a linkage with the diffusion limited process, and high frequencies have a linkage with the electron transfer limited process. At high frequencies,  $R_{sol}$  value is obtained. Warburg impedance increases

its visibility only at lower frequencies. On inhomogeneous, rough, or porous surfaces, CPE replaces  $C_{DL}$ . (Ahmed et al., 2014)

**Figure 2.** Randles electrical equivalent circuit model for full electrochemical system with two identical electrodes.  $R_{sys}$  is ohmic resistance of electrical wiring and  $C_{sol}$  is bulk capacitance.

In Figure 2  $C_{sol}$  is significant. The impedance is determined predominantly by a co-planar electrode system's capacitance, which relies on material, geometry, and permittivity of solution. The capacitance value has a big effect on system's impedance, regardless of whether the capacitance value is high or low.

### Impedance Spectroscopy

Electrochemical biosensors behave as a detector that can include EIS, and they have three different types according to their sensing method: impedimetric, amperometric, and potentiometric. Besides all these techniques that may contain EIS, impedimetric one mainly uses it. (Ahmed et al., 2014)

Biosensors based on EIS, which can be easily downsized, rapid, sensitive, and affordable, can be used in studies to determine the structural features of the solution/material that influence the permittivity and conductivity, or electrochemical reactions such as enzyme-catalysed reactions or specific binding reactions of some species on the surface of modified electrodes or in the solution. (Bahadır and Sezgintürk, 2016)

Pathogen and cell detection are also possible. Studies by Cheng et al. (2007), Shafiee et al. (2013), Toner et al. (2010), and Demirci et al. (2014) regarding impedance spectroscopy-based cell and virus detection and tracking with cell and virus lysate have been found in the literature.

## MATERIALS AND METHODS

### Chamber Design

Polymer-based microfluidic chips are well suited to move the impedance measurement processes forward. The design of the chips is made up of three layers; the bottom polymer layer with electrodes on it, the medium layer with double sided adhesive and a patterned channel, and the top polymer layer with inlet and outlet patterns.

#### Electrode Layer

The screen-printing technique is used to obtain the electrode layer and a silver paste mixture, which has highly conductive silver ink composition and is silicon adhesive, is applied on the flexible polymer surface. With a flexible hydrophobic polymer film from the protective cover film of double-sided adhesive (DSA), a mask pattern is formed. The pattern is created with the help of computer-aided design software, and a laser cutter is used. The mask is first positioned on a flexible hydrophilic polymer. On one side of the mask, the silver paste mixture is dropped. The mixture is spread on the mask by using a microscope glass slide as a squeegee. The open spaces are filled with the mixture.

After the screen-printing process, the mask is carefully taken away continued in baking at 80° for sixty minutes. The electrodes are ready at the end of the baking process. It is possible that at the end of the process, errors are unavoidable since the laser cutter cannot cut the polymer in its actual dimensions, and baking has also an effect on the size of the electrodes.

#### Channel layer

The channel layer, which is patterned on DSA and created by a CAD software, is to form a cavity for solution to be filled, and using constant volume of solution is crucial in impedance measurements.

#### Inlet layer

The inlet layer, which is designed in CAD software, is formed with the flexible hydrophilic polymer cut by the laser cutter. The chamber is assembled by removing the protective film from one side of DSA so that it is laminated.

In order to minimize errors, this process is repeated numerous times. There is no requirement to use complex and expensive devices during the process. The steps may be done in any environment.

### Experimental Setup

Probes of LCR meter, which is a device to measure the impedance, are attached to the electrodes of the chip, the sample solution is added into the channels, and magnitude and phase of impedance of the solution is recorded. The input AC potential is 1 peak-to-peak voltage ( $V_{pp}$ ) and AC frequency is between 100 Hz and 1 MHz. In this paper, the maximum difference value for impedance change is approximately 1 kHz, which means that the magnitude of impedance is 1 kHz.

### RESULTS

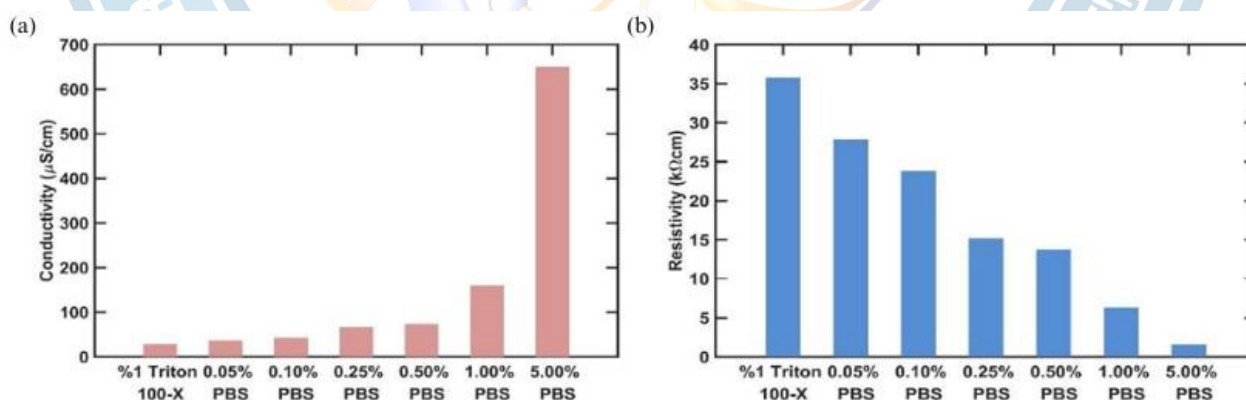

Even if the main purpose of this paper is to detect analytes, known conductance-valued solutions are measured firstly in order to obtain better knowledge about the system and impedance results. 1% Triton 100-X solution in DI pure water is used as control solution. Six test sample solutions, which are prepared at 0.05%, 0.1%, 0.25%, 0.50%, 1.0%, and 5.0% PBS in DI pure water, exposure to a conductivity test by using a conductivity meter.

Figure 3 (a) shows that different solutions with different concentrations have different conductivity levels. The determination of the resistivity for test samples and the control solution is done by impedance spectra measurements at a frequency range between 100 Hz and 1 MHz.

All the test samples and the control solutions are tested according to the procedure. For a solution 3 FFChips are used, and all the sample volumes are same with each other. The average of three impedance magnitude spectra measurements for a solution is calculated and this step is applied for all other solutions. According to the results, the Nyquist plot in Figure 4 is sketched.

### DISCUSSION

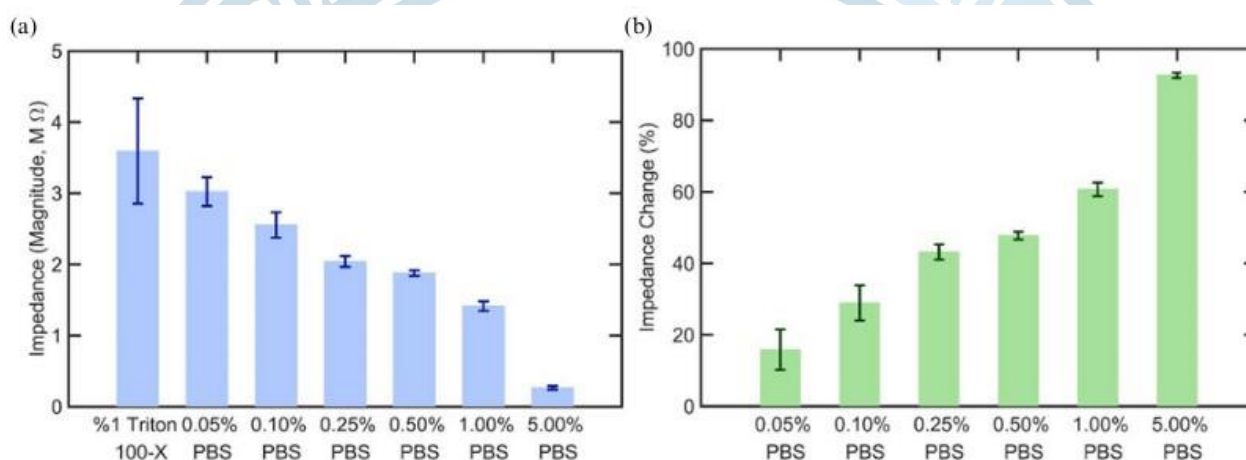

The definition of one of the electrical models of the FFChip was made, along with the background of the electrical impedance spectroscopy analysis system. DI and some concentrations of PBS solutions filled channel measurements were done. The results of these known-concentrated solutions demonstrated that the system is capable of detect even  $k\Omega$  of differences.

**Figure 3.** Test values a) Conductivity test values at various PBS concentrations b) Resistivity test values at various PBS concentrations.

**Figure 4.** Nyquist plot of impedance values of control solution and different PBS concentration-solutions for a frequency range between 100 Hz and 1 MHz.

**Figure 5.** a) Impedance magnitude values of all the solutions at 1 kHz. Error bars represent standard deviations (STD) of the mean of impedance magnitude. (n=3), b) The impedance magnitude changes of all the sample test solutions with respect to average control value at 1 kHz. Error bars represent standard deviations (STD) of the mean of impedance magnitude. (n=3)

## CONCLUSION

Lightweight, flexible, thin, affordable, easy to manufacture, disposable and mass-producible features make the flexible polymer film effective material for biosensors. With its portability, sensitivity, and rapid property, electrical impedance spectroscopy is efficacious in detection methodology.

## POSTER PRESENTATION

### Comparative study of the dietary habits of *Oedipoda coerulescens sulferegens* in two different regions of Tlemcen (Algeria)

Benmansour Bouchra Salima

University of Tlemcen

#### Abstract

The present work, of economic importance, concerns the diet of an Orthoptera species, *Oedipoda miniata*, in the natural conditions of 02 stations, in the region of Tlemcen (Algeria): the first in Sebdou (south of the wilaya of Tlemcen), and the other located at Moutass (South West of Tlemcen). For this, a floristic inventory of the plant species of the 02 study stations was carried out. This allowed us to highlight the main families. The faunistic inventory of Orthoptera reveals the presence of species belonging to the Acrididae family and to the Caelifera Order. The diet of *Oedipoda miniata* was performed by microscopic analysis of the faeces content. This is a method that is so far the most objective. Moreover, it does not disturb the demographic balance of the populations. The study of the diet allowed to observe in faeces a limited number plant species, consisting mainly of poaceae and lamiaceae. The interest of the study of the locust diet is to understand the phenomenon of competition and the existing relationship between the plant and the insect. In the wild, it is the means of knowing if the locust chooses its food facing a diversity of plants, or is it a question of availability and quantity.

**Key words:** Diet, Orthoptera, *Oedipoda miniata*, Sebdou, Moutass, Tlemcen, Algeria.

#### Introduction

Food is one of the most important ecological factors in various biological parameters orthopteran populations namely, the fertility, longevity, speed of development and birth rate (**DAJOZ, 1982**).

**DAJOZ (1971)**, considers food as a unique source of energy available to insects; it is obviously a limiting factor when it is in insufficient quantity. In addition, he notes that the diet of a species is rarely constant throughout the year and in all places.

According to **GILLON(1983)**, the use of food resources varies according to the environment in which the locust lives. The choice of the host plant is based not only on the insect-plant biochemical relationships but also on the structure of the environment. Similarly, **MOUMEN (1997)** states that the behavior of insects in the selection of the food substrate is a change in the opportunity to consume a plant rather than other. In fact, the choice of a plant by an insect depends on the presence of the substances stimulating or inhibiting food intake.

In the region of Tlemcen, more than 50 species have been described by **MESLI (2007)** and **DAMERDJI (2008)**. Most of these taxa belong to the family Acrididae including *Oedipoda miniata*. According to **MESLI (2007)**, aromatic and medicinal plants form a major part of the locust diet. **CHAPMAN (1982)** noted that the majority of phytophagous insects have more than 50% of oligophagous species or monophages (feeding on a single family of plants), against against Orthoptera and in particular locusts, 60% of species are called polyphagous and 25% are called graminivores. **PICAUD et al., (2003)** mention that rare are specialist Orthoptera species and that graminivorous species make their food choices because of the high content of grasses in sugar.

The study of the diet allowed us to know the trophic behavior of *Oedipoda miniata*. In the wild, this tells us if a locust attacks the most abundant plants or it remains a matter of preference. Thus, we used the method of the examination of the contents of faeces which is to compare the fragments of epidermis of the plants ingested by the insect with those of a reference collection prepared from existing plant species in its biotope. The determination of the diet, by the microscopic analysis of

the contents of the faeces remains until now the most objective. Moreover, this method does not disturb the demographic balance of populations. It is in this order of ideas that we chose to conduct this research.

## **Material and methods**

### **Choice of stations**

The choice of stations is based on the altitude parameter. Our study areas pass through the Tlemcen Mountains (Moutass) to the steppe region (Sebdou).

#### **Station 01: Moutass (Tlemcen Mountains)**

This station is located west of Tlemcen, with an exposure of 34.44'59.18"N and 1 ° 29'10.35"W, and an altitude of 1069 m. The recovery rate is 80%.

The climate of the region of Tlemcen among others Moutass, is of Mediterranean type, semi-arid in temperate winter, rainy in winter and dry in summer. Prolonged summer drought and erratic rainfall are ecological factors limiting and threatening the region's plant structures on a continuous basis.

#### **Station 02: Sebdou**

Sebdou is located south of Tlemcen wilaya, about 38 km. It lies between latitude 34 ° 38 'N and longitude 1 ° 19' W. This station has an exposure of 34.36'49.16"N and 1 ° 20'04.24"W, with an elevation of 966 m and a recovery rate exceeding 75%.

The climate of Sebdou is arid marked by two seasons: a winter which is short characterized by the irregular rainfall with mild temperatures; the other summer, long, dry, characterized by high temperatures and a significant lack of precipitation.

### **Study technique**

Samples are taken during the year 2015. The frequency of the exits is of once a month of two hours in each station, during the hot and sunny hours, a clear sky and a weak wind.

Two preliminary exits are carried out at least from December 2014 for vegetation sampling to establish a reference epidermothea.

### **Methods of studying vegetation**

For the study of floristic biodiversity, an exhaustive sampling was carried out in order to inventory all the plant species that exist in the 02 stations.

Thus, we have established the floristic characterization of the vegetation of the studied stations, from biological, morphological and geographical point of view. In addition, the development of an epidermotheque of references was duly realized.

### **Epidermotheque référence preparation**

Plant samples (leaves and stems) were collected at the study stations and returned to the laboratory. The fresh cuticles are gently removed from the underlying tissues, under the binocular magnifying glass, using fine forceps, or by placing the cuticle to be studied in contact with a glass slide, then scratching the other face until internal tissue (Benhalima, 1983). Several methods of preparation of epidermis are indicated such as those of STEWART (1965) in BENHALIMA (1983), LAUNOIS (1976), BUTET (1985), CHARA (1987).

The protocol of preparation of the reference epidermotheque follows the following diagram:

The epidermis was photographed using a microscope connected to a digital camera.

### **Study method of Orthoptera**

All the measurements were made in the form of a random walk within an approximate perimeter of 100m<sup>2</sup>. These samples are able to provide a good estimate of the faunistic richness.

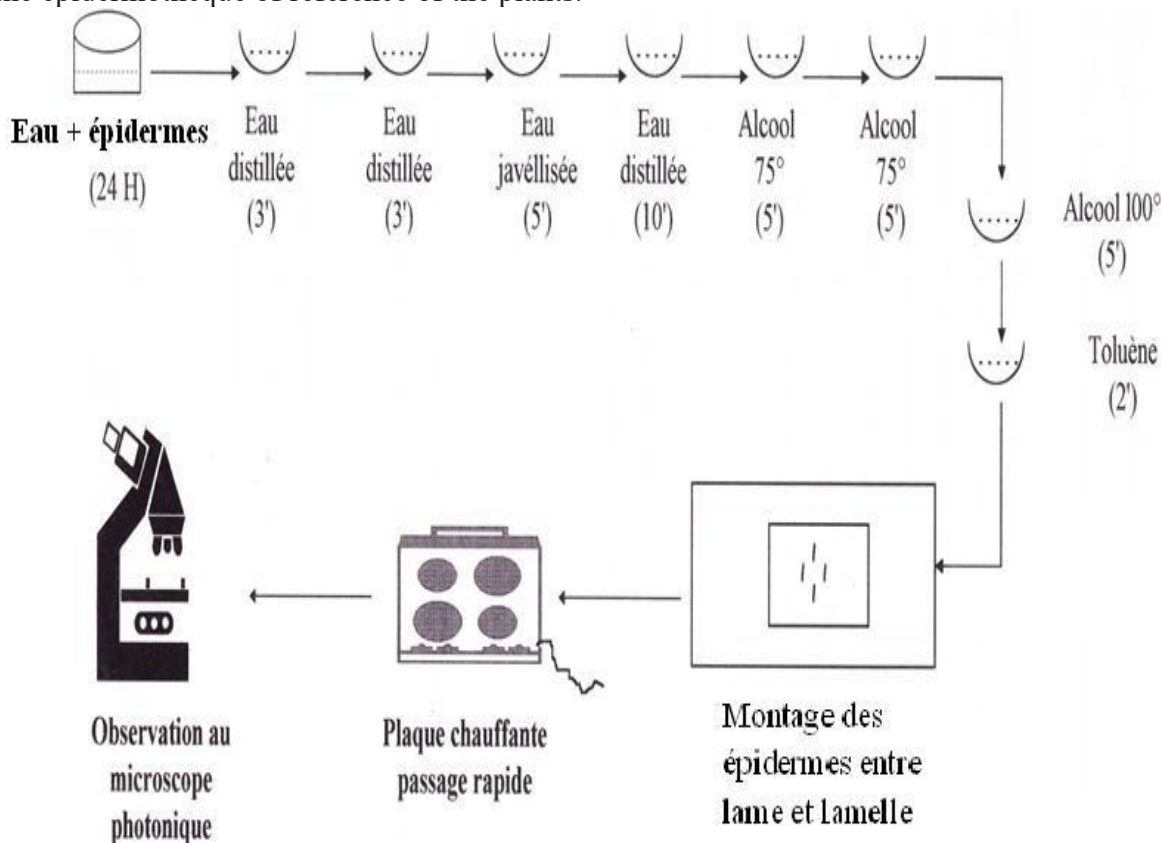

The determination of Orthoptera necessitated key works such as that of CHAUPARD (1943), the key to Orthoptera of North Africa, FELLAOUINE (1989), LOUVEAUX and BENHALIMA (1987) catalog of orthopterans of Acrididae in North Africa.

### **Feces analysis**

To determine the diet of *Oedipoda miniata*, we based on the composition of faeces. We therefore compared the plant fragments found in the feces of the species caught with the reference epidermothea prepared from the plant species collected in the different study stations. This method

has been widely used by many researchers including DOUMANDJI et al (1992), MESLI et al (2005), DAMERDJI (2008).

For this, individuals are harvested in the field and placed individually in plastic tubes and are put to rest for 8 hours (enough time to empty their digestive tract). The collected faeces are softened for 24 hours in water with wetting (polysorbate 80 or tween 80) and are then exposed to a series of baths. The experimental protocol of the preparation of the faeces is the same as that of the development of the epidermothèque of reference of the plants.

The fecal slide, once prepared, will be placed under a microscope, of which a 1mm<sup>2</sup> window is glued under the objective (Method of windows adopted by Professor Doumandji).

### III- Results and interpretations

#### Floristic composition

Table 1 illustrates the floristic composition of the two study areas.

**Table 1: Floristic composition by families and species of the 2 study stations**

Families	Species	Moutass	Sebdou
Anacardiaceae	<i>Pistacia lentiscus</i>	+	+
Apiaceae	<i>Ferula communis</i>	+	+
Astéraceae	<i>Scolymus sp.</i>	+	+
Borraginaceae	<i>Echium vulgare</i>	-	+
Caryophyllaceae	<i>Paronychia argentea</i>	-	+
Lamiaceae	<i>Ballota hirsuta</i>	+	-
	<i>Marrubium vulgare</i>	-	+
	<i>Phlomis herba-venti</i>	-	+
	<i>Rosmarinus officinalis</i>	+	-
	<i>Salvia officinalis</i>	+	+
	<i>Salvia verbanaca</i>	-	+
	<i>Thymus ciliatus</i>	+	+
Liliaceae	<i>Asparagus stipularis</i>	+	-
Palmaceae	<i>Chamaerops humilis</i>	+	-
Poaceae	<i>Ampelodesma mauritanicum</i>	+	-
	<i>Hordeum murinum</i>	+	-
	<i>Stipa tenacissima</i>	-	+
Résédaceae	<i>Reseda luteola</i>	-	+
Rhamnaceae	<i>Ziziphus lotus</i>	+	-

The results obtained show that the floristic procession is very diversified. Indeed, we counted 8 families in the stations of Moutass and Sebdou. Regarding the species richness, the two stations are diversified with 12 species each. From the floristic surveys, there are 19 plant species, 7 of which are from the Lamiaceae family, 3 from the Poaceae family.

The remaining species each belong to the remaining families. In total, there are 11 families. *Pistacia lentiscus*, *Ferula communis* and *Scolymus sp* are species found in both stations.

### Ecological indices

#### Global recovery

The total recovery rate of the environment is the sum of the recovery rates of all the plants present on 500 m<sup>2</sup>. It makes it possible to highlight the degree of occupation of the soil by the dominant species and to characterize the nature of the vegetal cover based on a scale proposed by DURANTON et al., (1982).

The results of calculations of plant species recovery rates evaluated at the two study stations are summarized in Table 2.

The formula considered most appropriate for estimating the degree of recovery is that of DURANTON et al (1982).

$$RG = \frac{\sum Ss}{s} \cdot 100$$

RG: overall recovery rate;

s: the surface of the plant transect;

Ss: the area occupied by a plant species projected orthogonally on the ground;

$$Ss = 3.14 r^2 n$$

r: mean radius of the tuft;

n: the number of tufts of the given species taken into consideration on the surface s.

**Table 2: Overall overlap of the two stations**

Station 1	RG%	Station 2	RG%
<i>Ampelodesma mauritanica</i>	22,68	<i>Stipa tenacissima</i>	33,21
<i>Hordeum murinum</i>	14,6	<i>Scolymus sp</i>	14,25
<i>Ziziphus lotus</i>	11,66	<i>Pile</i>	13,23
<i>Bahi</i>	10,52	<i>Thymus cilatus</i>	12,36
<i>Pile</i>	7,42	<i>Salof</i>	2,6
<i>Scolymus sp</i>	5,83	<i>Mavu</i>	1,92
<i>Rosmarinus officinalis</i>	3,52	<i>Phev</i>	1,79
<i>Chamaerops humilis</i>	3,1	<i>Ecvu</i>	1,83
<i>Feco</i>	2,18	<i>Relu</i>	1,6
<i>Thymus ciliatus</i>	1,92	<i>Feco</i>	1,2
<i>Salof</i>	1,15	<i>Salve</i>	0,88
<i>Aspst</i>	0,65	<i>Para</i>	0,4

In the first station, *Ampelodesma mauritanicum*, *Hordeum murinum*, and *Ziziphus lotus* are the most widespread, covering nearly 48.94% of the soil.

In the steppe region (station 2), *Stipa tenacissima* is the most representative species, covering 33.21%, followed by *Scolymus sp* with 14.25%.

#### Frequency of plant species in faeces

The principle is to note the presence or absence of the plant in the feces, according to BUTET (1985); it is expressed as follows:

$$F(i) = \frac{ni}{N} \times 100$$

F(i): The relative frequency of the epidermis contained in the feces, expressed as a percentage.

ni: The number of times the plant fragments (i) are present.

N: Total number of individuals examined.

#### Attraction index

This method tells us about the relationship between the actual consumption of a given plant species and its recovery rate in the field.

The technique involves cutting on a graph paper a square of 1 millimeter

side and stick it on the light microscope tray so that the lens is facing; then place the end of the lamella at the level of the square, slide it vertically millimeter by millimeter and column by column thus sweeping the whole surface.

For the computation of the index of attraction we used the following formulas proposed by DOUMANDJI (1993).

$$Ss = \sum xin / 'n'$$

$$S = \sum Ss / N$$

$$T = S / \sum S \times 100$$

$$IA = T / RG$$

Ss: Ingested area of a given plant species calculated for an individual.

Xi: surface of plant fragments, representing a given plant species.

n': scanned surface (sum of empty squares and solid squares).

n: surface of the lamella (400 mm<sup>2</sup>).

S: average total area of a given plant species calculated for all individuals.

N: number of individuals.

T: consumption rate of a given plant species.

IA: index of attraction.

RG: overall recovery for given plant species.

Table 3 and 4 summarizes the results of ecological indices in the two study stations.

**Table 3: Areas (mm<sup>2</sup>), relative frequencies (F%), consumption rate (T%) and attraction indices (AI) of plant species found in *Oedipoda miniata* feces in Station 1.**

**Picture card 2: Relative Frequencies and Consumption Rates of Species Found in the feces of *O.miniata* in station 1**

**Figure 3: Comparison between the attraction indices of species consumed by *O. miniata* and their overall recovery rates at station 1**

**Figure 4: Relative Frequencies and Consumption Rates of Species Found in the feces of *O. miniata* station 2**

**Figure 5: Relative Frequencies and Consumption Rates of Species Found in the feces of *O. miniata* in station 2**

## Discussion

At the Moutass station (Station 1), *O. miniata* consumes four plant species: *H. murinum*, *Z. lotus*, *R. officinalis*, and *P. lentiscus*. These species have a more or less low overall recovery; 22.6% for *H. murinum*, 11.66% for *Z. lotus*, 7.42% for *P. lentiscus* and 8.52

% for *R. officinalis*. The most consumed plant is *H. murinum* with a frequency of 59.48% and a consumption rate of 58.33%, followed by *R. officinalis* with  $F = 22\%$  and  $T = 22.86$ , *P. lentiscus* comes in third place with a frequency of 12.57% and a consumption rate of 11.94%, and finally, *Z. lotus* is placed fourth in the region of Moutasse with a frequency of 6.62% and a  $T$  equal to 7.31%.

We report that the consumption rate remains closely related to the relative frequency of plant fragments found in *O. faeces. miniata*.

Comparing the global recovery of plant species consumed by *O. miniata*, with their indices of attraction and their consumption rates, it appears that *H. murinum* (Poaceae) is the plant species most consumed by this locust, while *R. officinalis* (Lamiaceae) is the plant species that attracts it more with an index of attraction  $IA = 2.68$ ; *Z. lotus* with an  $AI = 0.62$  is the species that draws the least *O. miniata*. At the second station (Sebdou), 4 plant species form the floristic procession of *O. miniata*: *Stipa tenacissima*, *Pistacia lentiscus*, *Thymus ciliatus* and *M. vulgare*. The most consumed species is *S. tenacissima* with a consumption rate  $T = 50.65\%$ . Then comes *T. ciliatus* with a  $T = 22.51$ ; then *M. vulgare* with  $T = 22.07$ ; *P. lentiscus* being the least consumed species with  $T = 4.77\%$ . Although *M. vulgare*'s rate of recovery is the lowest (1.92%), it attracts more *O. miniata* because it has the highest  $AI$  (11.81).

## CONCLUSION

The study of the diet of the orthopteran *Oedipoda miniata* in the region of Tlemcen realized in two stations Moutass and Sebdou, revealed to us information on the behavior of this species vis-à-vis the present vegetation.

It is through the examination of the contents of the feces that we were able to realize the study of the diet (method of the window). This method is well suited for field research. It is simple, fast and objective

*Oedipoda miniata* has a clear preference for 7 plant species. Therefore, it is said that it is polyphagous. In addition, it is a stenophagus indicating a medium that is poor in plant species and is appreciated in degraded environments. Comparing the consumption rates with the relative frequency obtained in the present work, we note that the level of consumption is not proportional to the recovery rates in the field. This is reflected by the fact that plants with low recovery rates are sometimes overexploited.

The results confirm what has been mentioned in several works, saying that the choice of the plant is not due to its nutritional value, nor its abundance in the field. This is the case of *Rosmarinus officinalis* in the first station and *M. vulgare* in the second station. The results also show that the species *Oedipoda miniata* has a high affinity for plant species of the family Haceae (*Hordeum murinum*, and *Stipa tenacissima*) which it consumes more than 50%, and lamiacees (*Thymus ciliatus*, *Rosmarinus officinalis* and *Marrubium vulgare*) with a consumption rate exceeding 22%.

In both stations studied, *Oedipoda miniata* shows a very wide diet with a minimum of 4 plant species ingested per station. We can therefore call it a euryphage species.

#### Abstract

Cheese is considered a nutrient-rich food, important in the daily diet, but food-related diseases caused by cheese consumption have occurred in many countries. Moreover, in recent years the consumption of cheese in Albania has increased and along with this, the necessity of microbial risk assessments on cheese also increased. The purpose of this study was to evaluate the microbiological quality of samples of different categories of cheese, originating from 19 different regions of Albania. During the period 2013-2019, 484 cheese samples, (n=150), (n=294), (n=40) of them were the soft, semi-hard and hard type of white cheeses respectively were tested for hygiene indicators *E.coli* and *coagulase-positive staphylococci*, as well as the parameters of the indicator of *Salmonella spp.*, *Listeria monocytogenes*. The methods used were: ISO 11290: 2017 part one and two for *Listeria monocytogenes*, ISO 6579-1:2017 for *Salmonella spp.* and ISO 6888-1:2021 for *coagulase-positive staphylococci*. The results showed *coagulase-positive staphylococci* were found positive with a higher concentration above the legal criteria on 1.8 % (n=109), *E.coli* 13.2% (n=315). In addition, neither *Salmonella* nor *Listeria monocytogenes* were detected in 25 g to all types of cheeses (n=30 for both of them). This situation proves once again the importance and maximum care for ensuring a good hygienic quality of the milk used for cheese production, as well as the need for rigorous implementation of the Hazard Analysis Critical Control Point (HACCP) system in dairy processing plants.

**Keywords:** Cheese, *E.coli*, *Staph. coagulase positive*, *Salmonella.spp*, *Listeria monocytogenes*

#### INTRODUCTION

Cheese is one of the favorite products of Albanian consumers and is a good source of protein, calcium, vitamins, and minerals. It also contains vitamin E, vitamin K, riboflavin, vitamin B6, folate, vitamin B12, pantothenic acid, and betaine. In Albania, the production and consumption of natural cheese are growing from time to time. Natural cheese is produced by curdling raw or pasteurized milk from healthy dairy animals including cows, sheep, and goats. Cows' milk is most commonly used for cheese making, and natural cheese is one of the most commonly consumed foods of animal origin. Consumption of cheese is becoming popular (INSTAT, 2019). Table 1 shows the production of cheese in Albania (in tons), in the years 2014-2019.

**Table 1.** Cheese production in Albania (in tons), in the years 2014-2019

Cheese texture	YEARS

Cheese consumption has often been accompanied by reports of food outbreaks in various parts of the world, raising concerns about product safety (Sadik, C et al, 1986). Microbial populations present in raw milk can influence cheese quality dependent on the microbial profile and microbial load of the raw milk, ability of milk microflora to survive pasteurization, hygiene practices and build-up of microflora within the cheese manufacture plant, and additionally starter culture activity and acidity profiles, cheese manufacture technology, cheese compositional parameters, and ripening temperature/environments (Sheehan J, 2013; D'aoust, J et al 1985).

Recent studies from the year 2021 reported that O157 contamination was found in Gouda-like cheese (Hedberg C 1990). In recent years several outbreaks of human salmonella infection have been reported and cheese is a relatively uncommon way of transmission (Felip, G and Toti L 1984, EFSA 2019, Jackson K et al 2011, Jackson K et al 2011). Ready to eat (RTE) food contaminated with *Salmonella* and *Listeria monocytogenes* is considered a risk to public health. Salmonellosis was the second most commonly reported foodborne gastrointestinal infection in humans after campylobacteriosis and was an important cause of foodborne outbreaks in EUMS and non-MS countries (EFSA 2021).

In 2020, *Listeria monocytogenes* was the causative agent of 16 foodborne outbreaks at the EU level, involving seven MS and 120 cases of illness, 83 hospitalizations, and 17 deaths. Nine outbreaks were reported with strong evidence and 8 with weak evidence. The most commonly implicated food vehicles for the strong-evidence listeriosis foodborne outbreaks were fish and fish products, meat and cheese (Kousta, M et al 2010). Staphylococci are considered as indicator microorganisms for hygiene; therefore, their presence may be referred to neglected hygienic measures applied during production, processing and distribution of milk and dairy products.

The observed high levels of coliforms and *Escherichia coli* in dairy products are likely to indicate product contamination post pasteurization or inadequate pasteurization due to faulty equipment and lack of process monitoring. The presence of total coliforms and *Escherichia coli* in food of animal origin indicates environmental and fecal contamination, respectively.

Regulation (EC) No 2073/2005, and Albanian current Law on Food No.9863, 2008, lays down microbiological criteria, intended as food safety criteria (FSC) and process hygiene criteria (PHC), for *Salmonella* in specific food categories. According to current food law, the safety criterion for the products tested was the absence of *Listeria monocytogenes* in 25 g (Jackson, K., 2011). Cheeses should meet the safety criterion concerning *Listeria monocytogenes* and *Salmonella*; a product that does not comply with these two criteria is considered unsafe and cannot be offered for sale (ISO 16649-2: 2001). Compliance with these criteria must be legally verified by the individual food business operator (FBO) as part of their HACCP program, through own-checks when implementing the general and specific hygiene measures of Regulation (EC) No 852/2004 (Boyd E et al 2001).

## MATERIALS AND METHODS

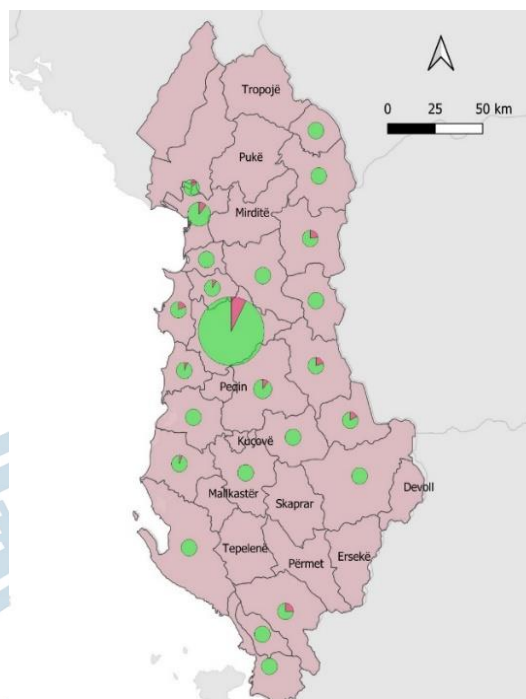

### -Study area and collection of cheeses samples.

During seven years of surveillance (2013-2019), a total of 484 cheese samples were analyzed as they were considered to be at risk by the health authority. All samples were collected as official control collected from 19 different regions covering almost all the Albanian territory (Figure 1) and were categorized according to their texture and productive properties.

Samples were collected randomly at retail and processing dairy facilities. All samples were divided into five sub units between 100 and 250 g of each aliquot and analyzed separately for each parameter. Representative samples were transported under cooling conditions in a refrigerated box with thermometer 4-6 °C within 24 h to the laboratories of Food Safety and Veterinary Institute and were tested for the presence of *Listeria monocytogenes*, *Salmonella spp.*, *E. coli* and coagulase positive staphylococci. The microbiological survey involved the sampling of a variety of cheese. Cheeses matrices were categorized according to their texture and manufacturing properties.

Of the total samples examined (484 samples): (n=150) of them were soft of white cheeses, including mozzarella, ricotta; (n=294) semi-hard, and (n=40) hard type samples include caciocavallo, cheddar, Emmental, gouda gruyere. (Table 2). It allows comparison between cheese texture and years of surveillance. Semi-hard cheese is the most analyzed sample (n=294) or 61.0%. In the year 2018, we analyzed 103 samples which is by far the maximum observed number following the year 2015 (96 samples).

**Figure 1.** The geographical data pertaining to the various sampling locations.

**Table 2.** Distribution in numbers of all types of white cheeses between the period 2013 -2019

Reporting year	Cheese texture tested			Total samples
	Soft	semi-hard	Hard	
2013	15	18	3	36
2014	28	30	4	62
2015	32	49	15	96
2016	15	26	1	42
2017	24	54	10	88
2018	27	72	4	103
2019	9	45	3	57
Total	150	294	40	484

#### -Microbiological assays

Samples were analyzed to evaluate the parameters according to European Union requirements (Commission Regulation EC No 2073/2005). The cheese was analyzed to evaluate the presence of food pathogens such as *Salmonella spp* (ISO I. 6579-1:2017), *Listeria monocytogenes* (ISO 11290-1:2017), and *Coagulase-positive staphylococci*. Bacteria belonging to the indicator families *coagulase-positive staphylococci* (ISO 6888-2: 1999) and *Enterobacteriaceae*, including *E. coli b-D-glucuronidase-positive* (ISO 16649-2: 2001), were also detected and enumerated.

#### - Detection of *Salmonella.spp*

*Salmonella* analyses were performed according to ISO 6579-1 (Standardisation, I. ISO I. 6579-1: 2017), Microbiology of the food chain— a horizontal method for the detection, enumeration and serotyping of *Salmonella*—Part one: Isolation methods usually involve two steps pre-enrichment and enrichment steps. Shortly, each sub unit of sample was inoculated in Buffered Peptone Water (Biolife, Viale Monza, Italy) as a primary dilution of 1:9. After the incubation at 37 °C for 24 h, a 0.1 mL of sample was transferred into Rappaport–Vassiliadis Broth (Biolife, Viale Monza, Italy) and incubated at 41.5° C for 24 h and 1 ml from incubated BPW was transferred in parallel in MKTTN broth. Bacterial growth compatible with *Salmonella spp.* was plated into two selective media, Xylose Lysine Deoxycholate (XLD) agar (Biomaxima, Lublin, Poland) and XLT4 (Condalab, Madrid, Spain) and incubated at 37° C for 24 h. All isolates were biochemically screened by using TSI (triple sugar iron agar) and a urea agar (Christensen).

#### - Detection of *Listeria monocytogenes*

ISO 11290: 2017 part one, were used for detection of *Listeria monocytogenes*. The two steps that include pre-enrichment and enrichment processes in selective culture media followed by biochemical identification of suspected *L. monocytogenes* colonies. First, 25 g of each cheese sample was added to 225 mL half Fraser broth

(Condalab, Madrid, Spain) for initial selective enrichment and homogenized in a stomacher (Seward 400, Radnor, PA, USA). Incubation followed at  $30^{\circ} \pm 1^{\circ} \text{C}$  for  $25 \pm 1 \text{ h}$  and after incubation 0.1 ml of the HF broth was transferred to tubes containing 10 ml of Fraser broth (Condalab, Madrid, Spain). Full-strength Fraser broth for the second enrichment, which was cultured at  $37^{\circ} \text{C}$  for  $24 \pm 2 \text{ h}$ . Both enrichment cultures (HF and Fraser) were streaked onto the chromogenic *Listeria* agar Ottaviani and Agosti (ALOA agar) and Oxford medium. The plates were incubated for 48 h at  $37^{\circ} \text{C}$  and observed for the presence of typical *Listeria* colonies.

- Enumeration of coagulase positive staphylococci

The cheese samples were investigated for coagulase-positive staphylococci enumeration by the analytical reference method ISO 6888-1:2021. By means of a sterile pipette, 0,1 ml of the initial suspension ( $10^{-1}$  dilution) were transferred to a Baird-Parker agar (BPA) plate. For enumeration, the number of Petri dishes were used according to the dilutions was refer into ISO 7218:2007. The dishes prepared was Inverted above and placed for  $24 \text{ h} \pm 2 \text{ h}$  in the incubator set at  $34^{\circ} \text{C}$  to  $38^{\circ} \text{C}$ , and then re-incubated for a total of  $48 \text{ h} \pm 4 \text{ h}$ . For confirmation were used, 0.3 ml of rabbit plasma and 0.1 ml of each BHI (Brain Heart Infusion), incubated at  $37^{\circ} \text{C}$ . Calculation of the number of coagulase-positive staphylococci per gram of product was performed from the number of confirmed colonies found on plates chosen at dilution levels that were a significant result.

- Enumeration of *E.coli* in TBX.

In order to quantify *E. coli*, the aliquots of 10 g of cheese were homogenized with 90 mL of sterile BPW and decimal dilutions were prepared (Biolife, Viale Monza, Italy). The homogenate was subjected to decimal serial dilutions using the same diluent in BPW and 1 ml of each dilution was plated on TBX agar medium (Biolife, Viale Monza, Italy). This medium included chromogenic substrates, X-glucuronide, for detecting dark blue colonies like *E. coli* that possess beta-glucuronidase activities. Expression of the results was done according to the ISO 7218. The mean of the values (cfu/g) of five subunits of each sample was calculated.

- Statistical approach

Descriptive analyses were used to summarize data such as frequencies and means, on types of cheese and hygienic conditions. IBM SPSS Version 20 (IBM Corporation, Armonk, NY) and Microsoft Excel 2013 (Microsoft Corporation, Redmond, WA) software packages were used in all analyses.

## RESULTS AND DISCUSSION

*Salmonella.spp.* (n=30) and *L.monocytogenes* (n=30) were not detected while coagulase positive staphylococci was found positive with a higher concentration above the legal criteria on 2 % for (n=109) (Table 3). This information highlights the need to develop preventive measures by selecting good milk quality. These results showed that 2 % of all types of cheeses samples were found unsatisfactory legal criteria. In addition, neither *Salmonella* nor *L. monocytogenes* were detected in 25 g in all types of cheeses.

**Table 3.** Pathogenic bacteria detection from all cheese samples

Parameter	white cheese texture			Total tested	(+ ve samp. (%))
	Soft	semi-hard	Hard		
<i>Salmonella spp.</i>	12	14	4	30	0
<i>L.monocytogenes</i>	7	8	15	30	0
<i>Coagulase pos staph.</i>	18	86 (2.3%)	5	109	5 (1.8%)
<i>E.coli beta-gluc(+)</i>	102 (13.2%)	195 (13.4%)	18 (10.5%)	315	42 (13.2%)
<b>Total</b>	<b>139</b>	<b>303</b>	<b>42</b>	<b>484</b>	<b>47 (15 %)</b>

In regards to *E.coli*, a total of 315 samples were inspected and results indicated that 42 (13.2%) showed higher levels above 100 cfu/g with the lowest and highest counts of 10 cfu/g- $10^5$  cfu/g, respectively. (Table 4). Also, 277 (86.8%) of the samples including the negative ones had *E.coli* lower than  $10^3$  cfu/g while the counts of the remaining 42 exceed  $10^3$  cfu/g. This table shows that 20 samples of cheese analysed for *E.coli* (6.3%) had counts between  $10^3$  -  $10^5$  cfu/g.

**Table 4. Safety status of traditional cheese in E.coli numbers**

<i>E.coli</i> levels	Soft cheese	Semi-hard cheese	Hard cheese	Total
Less than LOD	82	161	17	260
[1-10]	6	5	0	11
10-100	4	2	0	6
100-1000	5	15	2	22
1000-10000	4	9	0	13
10000-100000	5	2	0	7
Occur. over 10 <sup>2</sup>	13.2%	13.4%	10.5%	13.2%
Occur. lower than 10 <sup>2</sup>	86.8%	86.6%	89.5%	86.8%
Occur. between 10 <sup>3</sup> -10 <sup>4</sup>	8.5%	5.7%	0.0%	6.3%
<b>Total</b>	<b>106</b>	<b>194</b>	<b>19</b>	<b>319</b>

*Coagulase positive staphylococci*. A total of 110 samples were inspected for coagulase positive staphylococci. Among those with higher coagulase positive staphylococci growth, 3 samples out of 110 (2.7%) had the counts varying between 10<sup>1</sup> and 10<sup>4</sup> cfu/g (Table 5). Moreover, among these, two samples of semi hard cheese (2.3%) exceeded 10<sup>4</sup> cfu/g.

**Table 5. Safety status of traditional cheese in Staphylococcus numbers**

Staph. Levels	Soft cheese	Semi-hard cheese	Hard cheese	Total
less than LOD	17	85	5	107
[1-10]	0	1	0	1
10-100	0	0	0	0

Occurrence between 10 <sup>1</sup> -10 <sup>4</sup>	0.0%	3.4%	0.0%	2.7%

There is undoubtedly a connection between the microbiology of milk, dairy products, and their processing environments. The dairy processing industry must take care of the hygienic quality of the processing facilities, by implementing strict controls that ensure and protect the hygienic quality of its products.

There are different factors in microbial diversity within a dairy processing plant, which depend directly on various factors such as raw material, technological process, products, workers' activities, infrastructure, and the implementation of environmental sanitation practices. If the above is not applied, the possible pathogens present in these environments, as a result of mismanagement, provoke the production of unsafe food, and consequently in causing the outbreak of foodborne illness and economic loss for Food Business Operators.

## CONCLUSION

Raw milk cheese consumption is increasing in Albania also and worldwide with the growing demand for minimally processed, sustainable, healthy, and local foods. In this context, emerging and re-emerging pathogens once again represent a major food safety challenge. Therefore, good sanitation among plant workers, general sanitation in cheese plant, effective refrigeration, the use of active starters and good packaging are important in preventing related food poisoning from contaminated cheeses. Dairy processing plants should design and implement a food safety plan that carries out a risk analysis, preventive controls, monitoring procedures, and a corrective action plan. Also, training programs on good production practices for their employees are essential. Complete evaluation of the product chain of milk is also important for ensuring the hygienic quality of the cheese.

#### **Abstract**

*Pinus brutia* Ten. var. *pendulifolia* Frankis is a new variety of *Pinus brutia* Ten. commonly known as 'Kızılcım'. This species is an endemic species belonging to the Pinaceae family, which is mostly distributed in the Mediterranean and Aegean Regions. It has been reported that *Pinus* species are used in the treatment of respiratory and urinary system diseases, skin problems, diabetes, bronchitis, asthma, tuberculosis, cancer and gastrointestinal disorders such as reflux and ulcers. In this project, the phytochemical profile of *P. brutia* var. *pendulifolia* was determined by HPLC system and the antimicrobial activity of extracts prepared from the bark, leaves and green cones of *P. brutia* var. *pendulifolia* was investigated by microbroth dilution method, antioxidant activity by ABTS method and anti-inflammatory effect by COX-1, COX-2 enzyme inhibition method. The methanol extracts of *Pinus brutia* leaves, bark and green cone demonstrated antibacterial activity against Gram positive, Gram negative, and *Candida* species at concentrations between 312.5 and 2500 µg/mL. All of the extracts also showed strong antioxidant and anti-inflammatory activity, respectively with 57.14-72.14% and 50.63-88.13% inhibition at the 200 µg/mL concentration.

**Keywords:** *Pinus brutia*, Phytochemical, Antimicrobial activity, Antioxidant activity, Anti-inflammatory activity.

#### **INTRODUCTION**

*Pinus brutia* Ten. var. *pendulifolia* Frankis, a new variety of this species, is an endemic species belonging to the Pinaceae family (Güner et al., 2000) (Kızılarıslan and Sevgi, 2013), which is mostly distributed in the Mediterranean and Aegean Regions (Güner et al., 2000) (Kızılarıslan and Sevgi, 2013). It is known that *Pinus* species are used as antiseptic, tonic, expectorant and generally in respiratory and urinary system diseases, externally in the treatment of rheumatic pains and skin problems (Kızılarıslan and Sevgi, 2013). In addition, ethnomedicinally, *P. brutia* bark in decoction against diabetes, bronchitis, asthma, tuberculosis, cancer, gastrointestinal disorders such as reflux, ulcers, pneumonia, abscess, intestinal spasm and dyspepsia, as carminative; buds as expectorant, diuretic and against cough; cones as decoction in the treatment of respiratory system diseases such as bronchitis, asthma, gastrointestinal diseases such as dyspepsia and ulcers, pneumonia, diabetes and cancer; resin against diabetes, asthma, tuberculosis, cancer, reflux, ulcer, bronchitis and low back pain; trunk against tuberculosis and respiratory system disorders; and tar against tuberculosis, cancer, asthma, diabetes and bronchitis (Çakır, 2017). In addition, it is known that red pine tar is used externally and its roots and shoots are used as decoction as a wound healer (Kızılarıslan and Sevgi, 2013). This study was conducted to investigate the biochemical composition of *P. brutia* var. *pendulifolia* leaf, green cone and bark methanol extract and evaluate their biological activities, specifically in terms of antimicrobial, antioxidant, anti-inflammatory.

## MATERIALS AND METHODS

### Preparation of Plant Extracts

The leaves, green cone and bark of the *P. brutia* var. *pendulifolia* species, which is endemic to the Alanya (Antalya) and Fethiye (Muğla) regions in Turkey, were gathered in 2017, and identified by Forest Engineer Mahmut Tunahan. The extracts of *P. brutia* var. *pendulifolia* leaves, bark and green cone were acquired using the process of maceration using methanol at ambient temperature. The solvent was eliminated through the utilization of a rotary evaporator, resulting in the acquisition of desiccated extracts.

### Liquid-Chromatographic Analyses

The extracts were analysed by LC-MS/MS (Liquid Chromatography-Mass Spectrometry/ Mass Spectrometry) system to assess their phytochemical compositions.

### *In vitro* Anti-inflammatory Activity Test by COX-1 and COX-2 Enzyme Inhibition Method

The study was employed with COX-1 and COX-2 enzymes to assess the inhibitory effect of COX-1 and COX-2 *in vitro*. The quantification of prostaglandin E2 (PGE2) was conducted using the enzyme immunoassay (EIA) method, as described by Vazquez et al. (1997). The activity findings were evaluated using a colorimetric method in an ELISA microplate reader and expressed as a percentage of inhibition.

### Antimicrobial Activity Test

The antimicrobial activity of plant extracts was assessed using the microbroth dilution susceptibility assay developed by the Clinical and Laboratory Standards Institute (CLSI) (CLSI 2012, 2002a). The strains *Escherichia coli* (ATCC 35218), *Bacillus subtilis* (NRRL B478), and *Pseudomonas aeruginosa* (ATCC 27853) were cultured overnight at 37 °C on Mueller Hinton Agar (MHA), while *Candida albicans* (ATCC 10231) was cultured on Sabouraud Dextrose Agar (SDA) at 30 °C. The microbe cultures were adjusted to a concentration of  $1 \times 10^8$  colony-forming units per milliliter (CFU/mL) using McFarland 0.5 standard turbidity in a sterile saline (0.85%) solution. The cultures were then homogenized by vortexing. The plant extracts were dissolved in methanol to create the first stock solution. The plant extracts were made with varying concentrations using a two-fold serial dilution procedure in a 96-well microplate, ranging from 5000 to 4 µg/mL. Following the dilution procedure, 100 µL of each microbe culture were introduced into the well plates and subjected to incubation at 37 °C for 24 hours in the case of bacteria, and at 30 °C for 48 hours for yeast. Following the completion of the incubation period, the wells were subjected to staining by the addition of a 20 µL solution containing 0.01% resazurin. This staining process was employed to facilitate the visual differentiation between viable and non-viable cells, as indicated by the observed color variation, which ranged from blue (green) to pink. Ketoconazole, ciprofloxacin, and chloramphenicol were employed as standard agents to assess the antibacterial efficacy against *Candida albicans* and several bacterial species. The experiment was conducted on three separate occasions, and the outcomes were subsequently averaged.

### Antioxidant Activity Test

The method was employed by Re et al. (1999) involved the utilization of ABTS (2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonic acid)) to assess the antioxidant activity of plant extracts. A solution containing ABTS (7 mM) was prepared by dissolving it in water along with 2.45 mM of potassium persulfate. The resulting solution was then stored in a dark room for a duration of 16 hours. A standardized ABTS solution was made by diluting it with ethanol to achieve an absorbance value of  $0.70 \pm 0.002$ . Ethanol was utilized to generate stock solutions of plant extracts at a concentration of 200 µg/mL, ascorbic acid at a concentration of 100 µg/mL, and gallic acid at a concentration of 100 µg/mL. Ethanol was employed as the negative control, while ascorbic acid (Vitamin C) and gallic acid were utilized as the positive controls. The calculation of radical scavenging activity (RSA) involved determining the percentage inhibition of ABTS radical reduction using the following formula: "%ABTS scavenging = [(A control - A sample) / A control] × 100".

## RESULTS and DISCUSSION

### Liquid-Chromatographic Analyses

For LC-MS/MS analysis, Absciex 3200 MS/MS detector was used. The chromatographic separations were conducted using a Shimadzu 20A High Performance Liquid Chromatography (HPLC) system equipped with an ODS (octadecylsilane) column of 150 x 4.6 mm with a particle size of 3  $\mu$ m. The temperature of the column oven was adjusted to 40 °C, while the flow rate was set at 0.5 mL/min. The mobile phases utilized in the experiment consisted of two compositions: (A) a mixture of methanol, water, and formic acid in a volumetric ratio of 10:89:1, and (B) a mixture of methanol, water, and formic acid in a volumetric ratio of 89:10:1. The concentration of substance B underwent a significant increase, rising from 10% to 100% within a time frame of 40 minutes. The mass screening (EMS) was conducted within a selected mass range of 100-1000 amu. The findings were shown in Table 1.

### COX-1 and COX-2 Enzyme Inhibition Test

The *in vitro* anti-inflammatory activity of *P. brutia* var. *pendulifolia* leaves, green cone and bark methanol extracts was determined by COX-1 and COX-2 Enzyme Inhibition Test and % inhibition rates were determined (Table 2.). The 88.13% inhibition activity of green cone extract was determined at the 200  $\mu$ g/mL concentration. The fact that the result was similar with control group indicates that it has high anti-inflammatory activity.

**Table 2.** COX-1 and COX-2 Enzyme % inhibition rates

Concentration	100 µg/mL	200 µg/mL
	<b>% Inhibition</b>	
<i>P. brutia</i> var. <i>pendulifolia</i> leaf methanol extract	28.13	56.88
<i>P. brutia</i> var. <i>pendulifolia</i> green cone methanol extract	81.25	88.13
<i>P. brutia</i> var. <i>pendulifolia</i> bark methanol extract	45.00	74.38
<b>Selekoksisib</b>	<b>90.54</b>	<b>91.83</b>

### Antimicrobial Activity Test

The MIC values were given in Table 3. The minimum inhibitory concentrations of plant extract varied between 312,5-2500 µg/mL. According to the MIC values methanol extracts of *P. brutia* var. *pendulifolia* exhibited poor antimicrobial activity against only *Bacillus subtilis* with high concentrations. As a result, *Pseudomonas aeruginosa* is more sensitive than other bacteria species, similarly with *Candida albicans*.

**Table 3.** MIC values

	MIC µg/mL			
	<i>Escherichia coli</i>	<i>Bacillus subtilis</i>	<i>Pseudomonas aeruginosa</i>	<i>Candida albicans</i>
<i>P. brutia</i> var. <i>pendulifolia</i> green cone methanol extract	625	2500	312,5	312,5
<i>P. brutia</i> var. <i>pendulifolia</i> leaf methanol extract	625	2500	312,5	312,5
<i>P. brutia</i> var. <i>pendulifolia</i> bark methanol extract	625	2500	312,5	312,5
Ciprofloxacin	-	-	4	-
Ketoconazole	-	-	-	312,5
Chloramphenicol	8	4	-	

### Antioxidant Activity Test

All extracts of *P. brutia* var. *pendulifolia* exhibited high antioxidant activity compared with control groups of gallic and ascorbic acid (Table 4). The highest 72,14% inhibition activity was determined at the 200 µg/mL concentration with bark extracts.

**Table 4.** ABTS % inhibition rates

	ABTS % inhibition	Concentrations
<i>P. brutia</i> var. <i>pendulifolia</i> bark methanol extract	72,14	200 µg/mL
<i>P. brutia</i> var. <i>pendulifolia</i> green cone methanol extract	62,71	200 µg/mL
<i>P. brutia</i> var. <i>pendulifolia</i> leaf methanol extract	57,14	200 µg/mL
Gallic Acid	88,28	100 µg/mL
Ascorbic Acid	84,23	100 µg/mL

## CONCLUSION

This study aimed to analyze the phytochemical compositions of methanol extracts derived from the leaves, green cone, and bark of *P. brutia* var. *pendulifolia* using a High-Performance Liquid Chromatography (HPLC) system. Notably, this investigation represents the first attempt to examine these extracts in terms of their phytochemical composition. Furthermore, the extract's *in vitro* anti-inflammatory efficacy was investigated for the first time through the utilization of COX-1 and COX-2 enzyme inhibition techniques. The present study additionally assessed the antibacterial and antioxidant activities. The subsequent phase of the study involved the investigation of *in vitro* anti-inflammatory antimicrobial and antioxidant effects. The evaluation of their effects can be conducted by *in vivo* animal tests, which serve as an initial step in preparing for clinical research. It is also envisaged that the results obtained by developing phytotherapeutic formulations that can be alternative to the examples in the literature within the scope of the project outputs can be published in reputable scientific journals and congresses.
